running title: circadian clocks in the kidney

word count: abstract - 216 words; text – 3460 words

ABSTRACT

The circadian clock controls a wide variety of metabolic and homeostatic processes in a number of tissues, including the kidney. However, the role of the renal circadian clocks remains largely unknown. To address this question we performed a combined functional, transcriptomic and metabolomic analysis in mice with inducible and conditional ablation of the circadian clock system in the renal tubular cells (*Bmal1*^{lox/lox}/Pax8-rtTA/LC1 mice). Deep sequencing of the renal transcriptome revealed significant changes in the expression of genes related to metabolic pathways and organic anion transport. In parallel, kidneys from *Bmal1*^{lox/lox}/Pax8-rtTA/LC1 mice exhibited a significant decrease in the NAD⁺/NADH ratio suggesting an increased anaerobic glycolysis and/or decreased mitochondrial function. Metabolome profiling showed significant changes in plasma levels of amino acids, biogenic amines, acylcarnitines and lipids. In-depth analysis of two selected pathways revealed (i) a significant increase in plasma urea levels correlating with increased renal arginase 2 (Arg2) activity, hyperargininemia and increase of the kidney arginine content; (ii) a significantly increased plasma creatinine concentration and reduced capacity of the kidney to secrete anionic drugs (furosemide), paralleled by a ~80% decrease in the expression levels of organic anion transporter OAT3 (SLC22a8). Collectively, these results indicate that the renal circadian clocks control a variety of metabolic/homeostatic processes at both the intra-renal and systemic levels and are involved in drug disposition.

INTRODUCTION

The circadian timing system is an essential physiological regulatory mechanism that provides to cells, tissues, organs and, finally, to the whole organism, with an important functional advantage of anticipation of circadian changes in the environment that are imposed by the Earth's rotation. The circadian timing system is organized in a hierarchical manner, in that the central oscillator located in the suprachiasmatic nucleus of hypothalamus coordinates subsidiary oscillators located in peripheral tissues. On the molecular level, both the central and peripheral oscillators share a common molecular clock mechanism based on cell-autonomous and self-sustained transcriptional/translational feedback loops. This core clock mechanism controls circadian expression of so-called "output genes" that, in turn, impose cell-specific functional rhythms (reviewed in^{1,2}).

Previous studies have shown that the circadian timing system plays a major role in renal function. In mice, whole-body inactivation of different elements of the molecular clock leads to abnormal circadian patterns of urinary sodium and potassium excretion, loss of the circadian rhythmicity of plasma aldosterone levels and significant changes in arterial blood pressure (BP) (reviewed in³⁻⁵). In humans, growing evidence suggests a possible link between dysregulation of renal circadian rhythms and, development of hypertension and accelerated progression of chronic kidney disease. The importance of the circadian clock system in the kidney has been recently demonstrated on the molecular level. Zuber et al. and Nikolaeva et al. have shown that hundreds of transcripts in microdissected distal convoluted tubule and the connecting tubule (DCT/CNT) and, the cortical collecting duct (CCD) exhibit significant circadian oscillations in their expression levels and, that the whole-body inactivation of circadian transcriptional factor *Clock* leads to dramatic changes in the transcriptomes of the DCT/CNT and the CCD^{6,7}. Gumz and colleagues have shown that the circadian clock protein PER1 exerts diverse effects on the renal handling of sodium⁸⁻¹⁰. Zhang et al. have

demonstrated that among twelve tested mouse tissues, the kidney exhibits the second greatest number of circadian transcripts (the greatest number was found in the liver)¹¹. However, the role of the renal circadian clocks in the generation of functional and molecular rhythms in the kidney, as well as in the development of kidney disease remains largely unknown. To our knowledge, the only study that addressed this question is a recent paper by Tokonami et al. who showed that ablation of the circadian clock in renin-secreting granular cells results in several abnormalities, including increased glomerular filtration rate (GFR), decreased plasma aldosterone levels and low BP¹². Here, we studied the role of circadian clocks in the nephron by using conditional and inducible inactivation of BMAL1 protein, an indispensable element of the molecular clock (*Bmal1*^{lox/lox}/Pax8-rtTA/LC1 mice).

The renal tubular cells are involved in a wide variety of essential functions including maintenance of homeostasis, disposition of xenobiotics and synthesis of molecules that are released into the bloodstream (e.g. bicarbonate and arginine). Since many of these processes exhibit circadian rhythmicity, the aim of this study was to identify the molecular pathways/mechanisms that are directly controlled in the nephron by the tubular circadian clock. Using an approach combining functional, metabolomic and deep sequencing analyses we show that the tubular circadian clock is not a prerequisite for the control of the GFR or of the water, sodium and potassium balance. However, we demonstrate that the tubular circadian clock is deeply involved in the control of both, intra-renal and systemic metabolism and in drug disposition.

RESULTS

Validation of the *Bmal1*^{lox/lox}/*Pax8-rtTA/LC1* (cKO) knockout model. The conditional inactivation of the *Arntl* gene encoding BMAL1 was induced by 2-weeks treatment with doxycycline (DOX, 2 mg/ml in drinking water) of 8-weeks old *Bmal1*^{lox/lox}/*Pax8-rtTA/LC1* mice (hereafter referred to as conditional knockout mice or cKO mice). In parallel the same DOX treatment was provided to their littermate controls (*Bmal1*^{lox/lox} mice, hereafter referred to as Control mice). The qPCR analysis revealed that *Bmal1* mRNA expression was significantly reduced in kidneys of cKO mice (2 month after the end of DOX treatment, Supplemental Figure 1). Immunohistochemical staining for BMAL1 and CRE expression was performed at day 5 of the 2-weeks DOX treatment period or 2 month after the end of DOX treatment. As shown in Supplemental Figure 2, at day 5 of DOX treatment the CRE was ubiquitously expressed along the renal tubule but not in glomeruli or blood vessels in cKO mice. The BMAL1 protein was ubiquitously expressed in all kidney cells in Control mice, but in cKO mice all tubular cells became negative for BMAL1 staining at day 5 of DOX treatment (Supplemental Figure 3). The specific tubular inactivation of BMAL1 was maintained in cKO mice 2 month after the end of DOX treatment (Supplemental Figure 3). To assess the effect of BMAL1 deficiency on circadian mechanism *per se*, we performed qPCR analysis of expression levels of several genes involved in the core clock (*Cry1*, *Per2* and *Nr1d1*) and that of *Dbp*, an output gene that is directly controlled by the circadian clock. As shown in Supplemental Figure 1, the BMAL1 deficiency results in a significant attenuation in circadian oscillations of mRNA expression of *Cry1*, *Per2*, *Nr1d1* and *Dbp*. The expression level of *Bmal2*, a paralog of *Bmal1* which is thought to be able to rescue the BMAL1 deficiency in some tissues¹³, was increased in kidneys of cKO mice but the absolute levels of *Bmal2* expression remained significantly lower than those of other tested core clock

components (Supplemental Figure 1). Collectively, these results suggested that the activity of the circadian clock in renal tubular cells is significantly impaired.

PAX8 is a paired-box transcriptional factor crucial to the organogenesis and development of the kidney, the thyroid gland and the Müllerian system. Traykova-Brauch et al. used a partial *Pax8* promoter to target the expression of a tetracycline-dependent transactivator (tTA) to the renal tubular cells¹⁴. The tissue-specificity of the promoter-driven expression was assessed in the kidney, liver, heart, lung, brain, spleen, thyroid and colon. Among the tissues tested, the Pax8-driven CRE expression was found all along the renal tubule and in a subset of periportal hepatocytes. Hence, we tested the BMAL1 expression in the liver. As shown in Supplemental Figure 4, indeed some proportion of liver cells located in the vicinity of large blood vessels appeared negative for BMAL staining in DOX-treated cKO mice.

Basic characteristics of cKO mice. To avoid the potential side effects related to DOX toxicity all further analyses were performed 2 month after the end of DOX treatment. For all experiments mice were adapted to a 12-hour light/12-hour dark cycle for 2 weeks.

The cKO mice were overtly normal, their body weight was not different from the Control mice but their kidney weight/body weight ratio was significantly decreased (Table 1). The basic morphological analysis did not reveal any obvious renal abnormalities in cKO mice (tested parameters: gross renal morphology, interstitial fibrosis, glomerular sclerosis, inflammation, vascular lesions; data not shown).

Blood collection was performed at ZT4 and ZT16 (ZT – Zeitgeber time units; ZT0 is the time of light on and ZT12 is the time of light off). Twenty-four hour or hourly urine was collected from freely moving mice housed in metabolic cages with free access to food and water. As shown in Table 1, the only difference found in 24-hour urine samples was a

significant reduction in urinary pH in cKO mice. Since the whole body knockout of *Clock* results in a significantly different circadian kinetics of urinary water, sodium and potassium excretion, we also analyzed the hourly urine excretion pattern in Control and cKO mice. To exclude the influence of light on urine excretory rhythms, the hourly urine collection was also performed on animals placed in constant darkness 30 hours before urine collection (dark-dark conditions). As shown in Supplemental Figures 5 and 6 the circadian patterns of urinary excretion of water, sodium and potassium were not different between Control and cKO mice in both light/dark and dark/dark conditions, respectively. Basic analysis of plasma samples revealed a significant increase in creatinine (ZT4 and ZT16), urea (ZT4 and ZT16) and magnesium (ZT16) levels and of osmolality (ZT16) in cKO mice (Table 1, *t*-test). Differences between ZT4 and ZT16 for plasma parameters were analyzed by 2-way ANOVA. As shown is Supplemental Table 1, ANOVA revealed a significant effect of time on plasma osmolality and plasma concentration of sodium, potassium, calcium, creatinine, urea and aldosterone. This effect of time was similar between Control and cKO mice. Importantly, there was no difference in the GFR between Control and cKO mice, as measured by inulin clearance (Table 1). The cKO mice showed a modest but statistically significant decrease in systolic BP (FDR<0.001), but not in diastolic BP; the inactive phase BP dipping was not different between Control and cKO mice (Supplemental Figure 7 and Supplemental Table 2).

Deep sequencing kidney transcriptome profiling and plasma metabolome analysis of Control and cKO mice. The increased plasma creatinine and urea levels along with normal GFR suggested a tubular impairment in cKO mice. Since the circadian clock has been shown to control a variety of physiological processes, we performed unbiased kidney transcriptome and plasma metabolome analyses in Control and cKO mice in order to identify metabolic/homeostatic pathways and/or transporter systems that are controlled by the renal

circadian clock. Transcriptome profiling of RNAs extracted from the whole kidney (ZT4 and ZT16) was performed by deep sequencing and the partial metabolome profiling (180 plasma metabolites from five substance classes, i.e. hexose, amino acids, biogenic amines, acylcarnitines, and lipids; BIOCERATES Life Sciences AG, Innsbruck) was performed on plasma samples collected at ZT4 and ZT16.

For each sample, from 34 to 50 million sequencing reads were aligned to the mouse genome (Supplemental Table 3). As shown in Figure 1A, 721 and 765 transcripts exhibited differential expression levels between Control and cKO mice at ZT4 and ZT16, respectively (FDR<0.05, Supplemental Table 4). Among them, 552 transcripts were commonly changed at ZT4 and ZT16 (Figure 1A and Supplemental Table 4). Gene ontology (GO) analysis with these 552 genes followed by summarization in REVIGO¹⁵ revealed enrichment of processes related to the cellular metabolism (carboxylic acid metabolism cluster, blue box, Figure 1B and Supplemental Table 5) and organic anion transport (organic anion transport cluster, pink box, Figure 1B and Supplemental Table 5). Differential expression of six selected genes, namely nicotinamide phosphoribosyltransferase (Nampt), peroxisome proliferator-activated receptor delta (Ppard), mitochondrially encoded NADH dehydrogenase 1 (mt-Nd1), carnitine transporter Slc22a5, monocarboxylate transporter 1 (Slc16a1, or Mct1) and cyclin-dependent kinase inhibitor 1a (Cdkn1a, or p21) was validated by qPCR (Supplemental Figure 8). Analysis of transcripts encoding proteins located in mitochondria demonstrated that transcripts encoded by both mitochondrial and nuclear genomes are significantly overrepresented among the most down-regulated genes in cKO mice, at both ZT4 and ZT16 ($p<0.001$, two-tailed Mann-Whitney *U* test, Supplemental Figure 9). Because the circadian clock has been shown to control mitochondrial biogenesis¹⁶ we performed a quantitative analysis of mitochondrial genomic DNA in kidneys of Control and cKO mice. As shown in Figure 2A, the mitochondrial DNA content was not different between Control and cKO mice.

The NAD⁺/NADH ratio, a marker reflecting oxidative phosphorylation/glycolysis ratio, was significantly decreased in the kidney of cKO mice but not in the liver (Figure 2B).

Metabolome analysis revealed significant difference in the plasma levels of amino acids (arginine (ZT16), glutamate (ZT4) and methionine (ZT 16)), biogenic amines (asymmetric dimethylarginine (ADMA, ZT16); creatinine (ZT4 and ZT16 (thereby confirming results of blood chemistry analysis, see Table 1)); carnosine (ZT16) and taurine (ZT16)), carnitine (C0, ZT4 and ZT16) and several acylcarnitines, and of different species of phosphatidylcholine, lysophosphatidylcholine and sphingomyeline (Supplemental Table 6).

Comparison of metabolome and transcriptome data allowed us to identify several potential mechanisms through which the tubular circadian clocks participate in the control of blood metabolome. Mechanisms involved in the control of plasma urea/arginine and creatinine levels were selected for validation and more in-depth analysis.

Urea and arginine The urea is the end product of ammonia detoxification in the liver, a process that depends on the activity of Arginase I, an enzyme that converts *L*-arginine formed in the liver urea cycle into urea and *L*-ornithine. The kidney expresses the second arginase isoform, namely Arginase II (ARGII), but its activity is significantly lower than the activity of ARG I in the liver. Hence, it is generally accepted that in the normal physiological state ARGII does not influence plasma urea levels¹⁷. Most of the circulating *L*-arginine is synthesized in the kidney proximal tubule from *L*-citrulline that is absorbed from the small intestine.

Analysis of transcriptomes revealed that ArgII transcript levels are significantly upregulated in kidneys of cKO mice (Supplemental Table 5 and Supplemental Figure 10A). Western blotting performed on microdissected renal tubules (Figure 3A and Supplemental Figure 10B) and immunohistochemical staining (Supplemental Figure 10C) demonstrated that

ARGII protein expression is dramatically increased specifically in the proximal straight tubule (PST). As shown in Figure 3B, the enzymatic arginase activity was significantly increased in kidneys of cKO mice and reached ~25% of arginase activity in the liver; the liver arginase activity was not different between Control and cKO mice. In parallel, arginine levels in kidney tissue of cKO mice were significantly increased (Figure 3C), thereby providing a potential link with hyperargininemia in cKO mice demonstrated in the metabolomic profiling (Supplemental Table 6). Interestingly, the activity of the nitric oxide synthase, the second major arginine consuming enzyme in the kidney¹⁸ was also significantly increased in cKO mice (Figure 3D).

Creatinine and furosemide

Creatinine, a weak organic acid, is eliminated in the urine by glomerular filtration and, in part, by tubular secretion. Vallon et al. have shown that organic anion transporter 3 (OAT3 (Slc22a8)) significantly contributes to the creatinine secretion in the mouse kidney¹⁹. Analysis of transcriptome revealed that OAT3 expression is reduced in cKO mice at both ZT4 and ZT16 (Supplemental Table 4). These results were confirmed by qPCR (Figure 4A). Western blotting demonstrated ~ 80% reduction in OAT3 protein expression in cKO mice (Figure 4B, p=0.004). Since OAT3 is involved in the basolateral transport of a variety of organic acids, including several clinically important drugs, we tested the possibility that the tubular circadian clocks controls pharmacological properties of furosemide, a diuretic which is actively secreted in the kidney by OAT3. As shown in Figure 4C, the cKO mice exhibited rightward shift in the natriuretic dose-response curve for furosemide (Control mice: IC50=0.117±0.048 µg furosemide/g BW; cKO mice: IC50=0.263±0.094 µg furosemide/g BW, Mean±SD; n=5, p=0.012, t-test). In parallel, cKO mice showed lower urinary furosemide excretion following a single 0.3 µg /g BW furosemide bolus (Figure 4D).

DISCUSSION

An intriguing result of this study is that the renal phenotype of cKO mice differs significantly from that of *Clock*-null mice⁷. The major difference consists in the normal circadian dynamics of urinary water, sodium and potassium excretion, normal plasma aldosterone levels and normal GFR in cKO mice, whereas these functions were significantly impaired in *Clock*-null mice. This difference suggests that either the tubular circadian clocks are not involved in the generation of urinary excretory rhythms or, that the inactivation of tubular circadian clocks could be fully compensated by other mechanisms. These findings raise the question about the tissue/cellular origin of renal excretory rhythms. Okamura and colleagues²⁰ showed that mice lacking Cry1 and Cry2 exhibit hyperaldosteronism and blunted circadian oscillations in plasma aldosterone levels due to increased aldosterone synthesis in adrenal glands. We have recently shown that the deletion of *Arntl* in renal granular cells results in modified circadian rhythm of urinary sodium excretion, polyuria, increased GFR and low BP¹². Accumulating evidence from Titze, Luft and colleagues²¹ suggest that total body sodium content fluctuates independently of intake or body weight, thereby pointing to a possible role of extracellular sodium storage/release dynamics. Also, there is strong evidence that the circadian rhythms of urinary potassium excretion are determined, at least in part, by the net potassium fluxes between intracellular and extracellular compartments²². Collectively, these results suggest that circadian clocks in many different organs/cell types may participate to the generation/maintenance of circadian rhythms of urinary sodium, potassium and water excretion, but the role of the intrinsic renal tubular clocks in these processes remains yet unclear.

However, we found that the tubular circadian clock is deeply involved in several other essential physiological functions including control of both the intra-renal and systemic

metabolism, elimination of xenobiotics/drugs and maintenance of homeostasis of compounds secreted into the blood by the kidney. The critical role of the circadian clock system in the control of metabolism has been demonstrated in a number of tissues²³; however, the novelty of our study is that the suppression of the tubular circadian clock greatly impacts plasma metabolome, in a way that in turn may affect metabolic and homeostatic processes at the systemic level. Our partial metabolome analysis covered less than 5% of the total plasma metabolome estimates (180 vs ~4'000 metabolites, respectively), but even this restricted approach allowed us to identify more than 50 metabolites that are differentially represented in plasma of cKO mice.

Comparison of transcriptome and metabolome data allows establishing tubular mechanisms that are disturbed in cKO mice. For instance, carnitine deficiency in cKO mice correlates with significantly decreased expression of the Scl22a5 carnitine transporter involved in the carnitine reabsorption in the proximal tubule. Of note, the loss-of-function of Slc22a5 is a well-known cause of primary carnitine deficiency²⁴. Two of these mechanisms, namely, those that are involved in the renal control of plasma creatinine and urea levels were selected for in-depth analysis. These two mechanisms were chosen because (i) plasma creatinine and urea concentrations are commonly used as surrogate biomarkers of glomerular (dys)function in clinical settings, and (ii) because creatinine secretion in the kidney occurs through the same transporter systems as those used by many clinically important drugs (see below).

We found that the increase in plasma urea levels correlates with tubular and not with glomerular dysfunction. We show that cKO mice exhibit a parallel increase in the renal Arginase II (ARG2) activity and renal and plasma arginine levels. Arginine, a semi-essential amino acid, is synthesized in the proximal convoluted tubule and released into the blood stream where it can be, in part, recovered by the proximal straight tubule and converted to

urea and *L*-ornithine by ARG2, or oxidized to nitric oxide and *L*-citrulline by NO synthases in tubular and non-tubular renal cells¹⁸. Interestingly, the activity of the NO synthase was also significantly upregulated in kidneys of cKO mice. Collectively, these results suggest that the circadian clock in tubular cells controls both the intra-renal arginine metabolism and systemic arginine and urea levels.

Similarly, we found that the increase in plasma creatinine levels has tubular origin and results from the decreased expression levels of OAT3. This finding has a second important facet that supports the link between the circadian clock and the pharmacokinetics of drugs. The OAT3 transporter is involved in tubular secretion of a variety of clinically important drugs including diuretics (furosemide, bendroflumethiazide), antiherpetics (acyclovir), antiretrovirals (tenofovir), antineoplastics (methotrexate), antibiotics (benzylpenicillin) and many other (reviewed in²⁵). Here we show that the reduced expression of OAT3 in cKO mice correlates with less potent natriuretic effect and lower rate of urinary elimination of furosemide, a diuretic which is not filtered in glomeruli and must be secreted into tubular lumen to inhibit the Na/K/2Cl co-transporter. To our knowledge, this is the first demonstration that the renal circadian clocks are involved in drug pharmacokinetic. Hence, together with the well-documented effects of the circadian clock on drug metabolism in the liver²⁶, drug absorption in the intestine²⁷ and drug distribution²⁸ our study shows that the circadian timing system interferes with drug pharmacokinetics at very different levels and highlights the attention that must be given to chronopharmacology and chronotherapy.

CONCISE METHODS

Animals The procedures used to generate and the characterization of *Bmall*^{lox/lox}, Pax8-rtTA and LC-1 Cre mice were described previously¹⁴. The three mouse lines used in this

study are inbred strains, bred on the genetic background of the C57BL/6J mouse. The animals were maintained *ad libitum* on the standard laboratory chow diet (KLIBA NAFAG diet 3800). Before all experiments, mice were adapted to a 12-hour light/ dark cycle. All experiments with animals were performed in accordance with the Swiss guidelines for animal care, which conform to the National Institutes of Health animal care guidelines.

Antibodies Anti-CRE recombinase antibody was from Novagen. Anti-BMAL1 antibody was described elsewhere¹². Anti-ARG2 antibody was from Santa Cruz Biotechnology. Anti-actin antibody was from Sigma-Aldrich. Anti-OAT3 (SLC22a8) antibody was from Abcam. Anti-OCTN2 (SLC22a5) antibody was from GeneTex. Immunohistochemistry and Western blotting protocols were identical to those described previously¹².

Metabolic cages Mice were housed in individual metabolic cages (Tecniplast). Urine collection was performed after a 3-day adaptation period. Urine and blood chemistry was analyzed as previously described⁷. Hourly urine collection was performed as previously described⁷.

Blood and urine chemistry Partial plasma metabolome profiling (180 plasma metabolites from five substance classes, i.e. hexose, amino acids, biogenic amines, acylcarnitines, and lipids) was performed by BIOCERATES Life Sciences AG (Innsbruck). Plasma aldosterone levels were measured by radioimmunoassay (DPC).

Measurements performed on kidney and/or liver tissue extracts The NAD⁺ and NADH levels in kidney and liver tissue were determined by PicoProbe colometric kit from BioVision. Kidney tissue spermine levels were determined by Ansynth Service B.V. (Netherland). Kidney tissue L-arginine levels were determined by kit from MyBioSource. Arginase activity in the kidney and liver tissues was determined as arginase-specific urea

formation from ^{14}C -L-arginine as previously described^{29, 30}. NOS activity was determined as NOS-specific L-citrulline formation from ^{14}C -L-arginine as described in Supplementary Methods.

BP The BP was measured in conscious unrestrained mice using telemetry (DSI system).

GFR The GFR was determined according to the method described by Qi et al.³¹.

Gene analysis by RNAseq (see Supplementary Methods)

Natriuretic effect of furosemide and furosemide dosage These experiments were performed according to the protocol established by Vallon et al.³².

FIGURE LEGENDS

Figure 1. Deep sequencing transcriptome analysis of kidneys from Control and cKO mice.

A. Heat maps of normalized expression values of genes significantly affected in kidneys of cKO mice at ZT4, ZT16 or both time points (FDR < 5%). Expression values were mean centered, variance normalized and subjected to hierarchical clustering (complete linkage) using Pearson correlation as similarity metric. **B.** Gene ontology analysis showing significantly enriched biological processes (Bonferroni correction) among the 552 genes differentially expressed in kidneys of Control and cKO mice at ZT4 and ZT16. Significant biological processes were summarized and classified with REVIGO.

Figure 2. Altered renal metabolism in cKO mice. **A.** Quantification of mitochondrial DNA (mtDNA) in kidneys of Control and cKO mice (ZT8). Relative amounts of mtDNA and nuclear DNA were quantitated by qPCR of mitochondrial NADH dehydrogenase 1 (*mt-Nd1*) and nuclear *Ppia* (cyclophilin) genes ¹⁶. Mean±SD, n=6, Student's t-test. **B.** NAD⁺/NADH

ratios in the kidney (ZT12) and the liver (ZT12) of Control and cKO mice. Mean \pm SD, n=6, Student's t-test.

Figure 3. Altered arginine production/degradation in cKO mice. **A.** Western blot analysis of ARG2 protein expression in the proximal straight tubules (PST) microdissected from kidneys of Control and cKO mice (ZT8). 3 mice/genotype were used for this analysis. **B.** Arginase activity in the kidney (ZT0) and the liver (ZT0) of Control and cKO mice. Mean \pm SD, n=3, Student's t-test. **C.** L-arginine levels in kidney tissue of Control and cKO mice (ZT8). Mean \pm SD, n=6, Student's t-test. **D.** NOS-specific L-citrulline formation in kidney tissue of Control and cKO mice (ZT8). Mean \pm SD, n=6, Student's t-test.

Figure 4. Lower OAT3 mRNA and protein expression correlates with impaired natriuretic response to furosemide and decreased urinary excretion of furosemide in cKO mice. **A.** qPCR analysis of Oat3 (Slc22a8) mRNA expression in kidneys of Control (open circles) and cKO (filled circles) mice. Mean \pm SD, n=6. **B.** Western blotting with anti-OAT3 or anti-GAPDH antibodies on protein extracts prepared from kidneys of Control and cKO mice (n=5 mice in each group), ZT16. **C.** Rightward shift in the natriuretic response to furosemide in cKO mice. Mean \pm SEM, n=5. The IC50 values were calculated using the GraphPad PRISM 6 software; v - vehicle. ZT16. **D.** Lower urinary excretion of furosemide in cKO mice. Furosemide was dosed in the urine collected during 10 min followed the 0.3 μ g/g BW furosemide bolus. Mean \pm SEM, n=8. Student's t-test.

Table 1. 24h-urine and plasma chemistry in Control and cKO mice

	Control	cKO	p

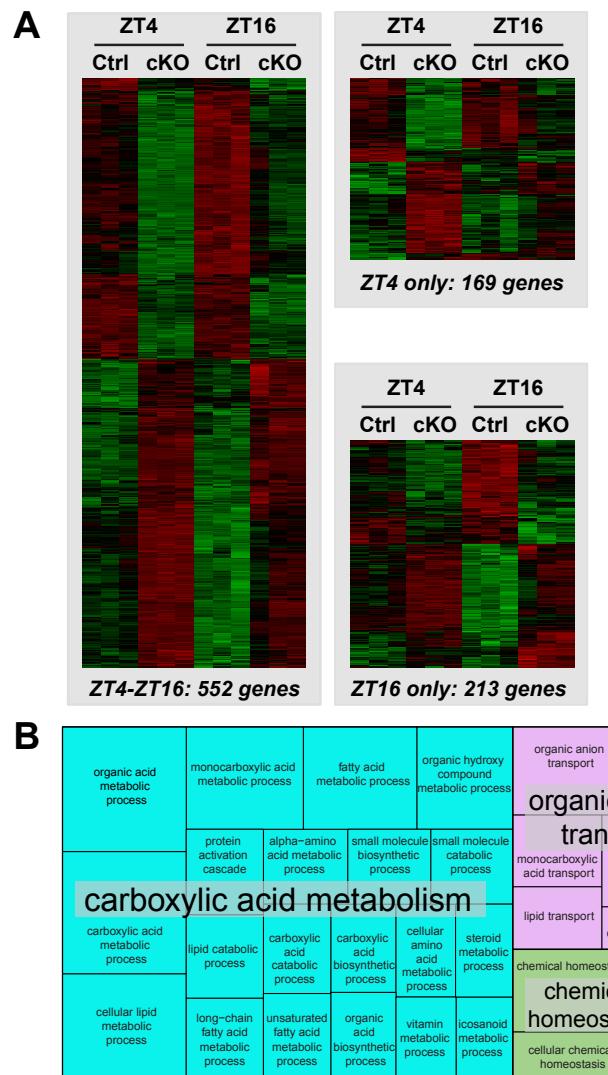

Figure 1, Nikolaeva et al.

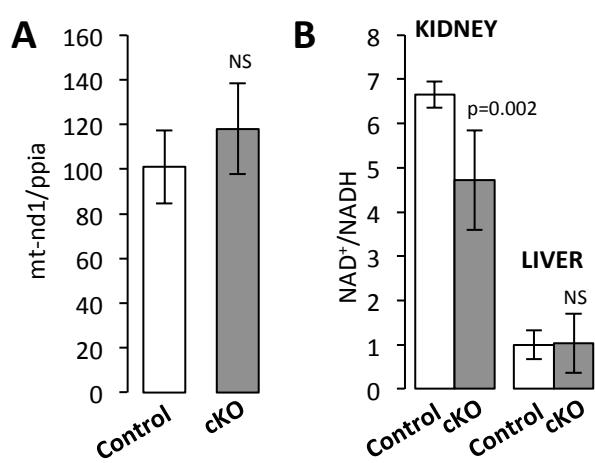

Figure 2, Nikolaeva et al.

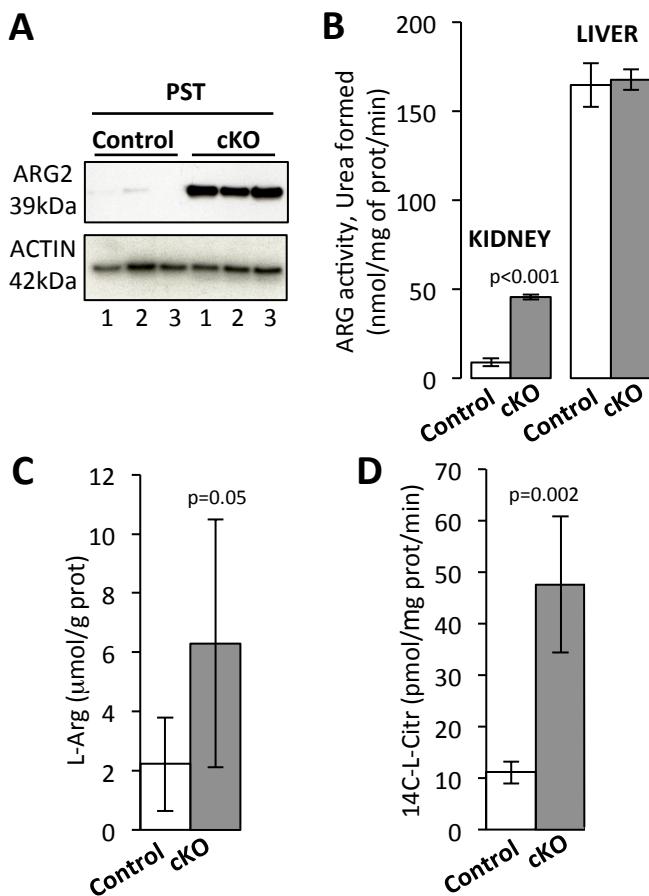

Figure 3, Nikolaeva et al.

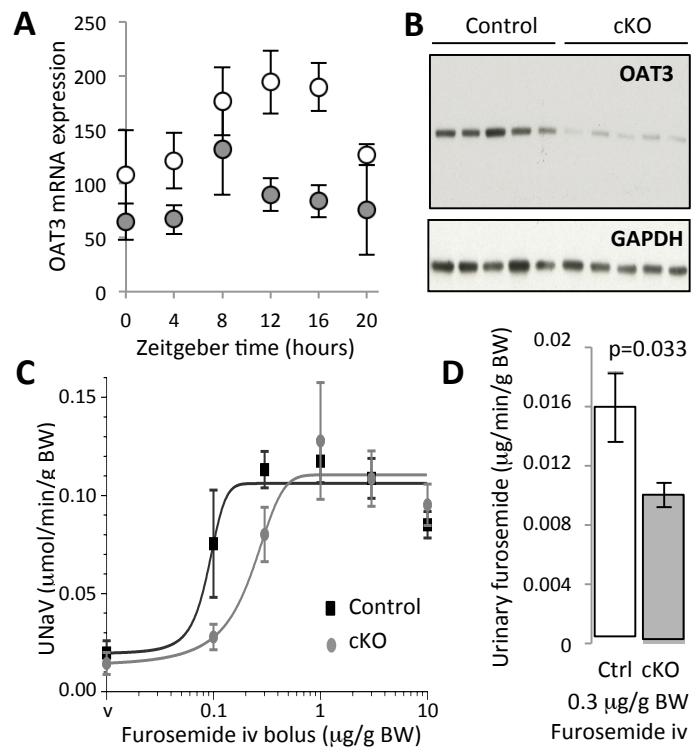

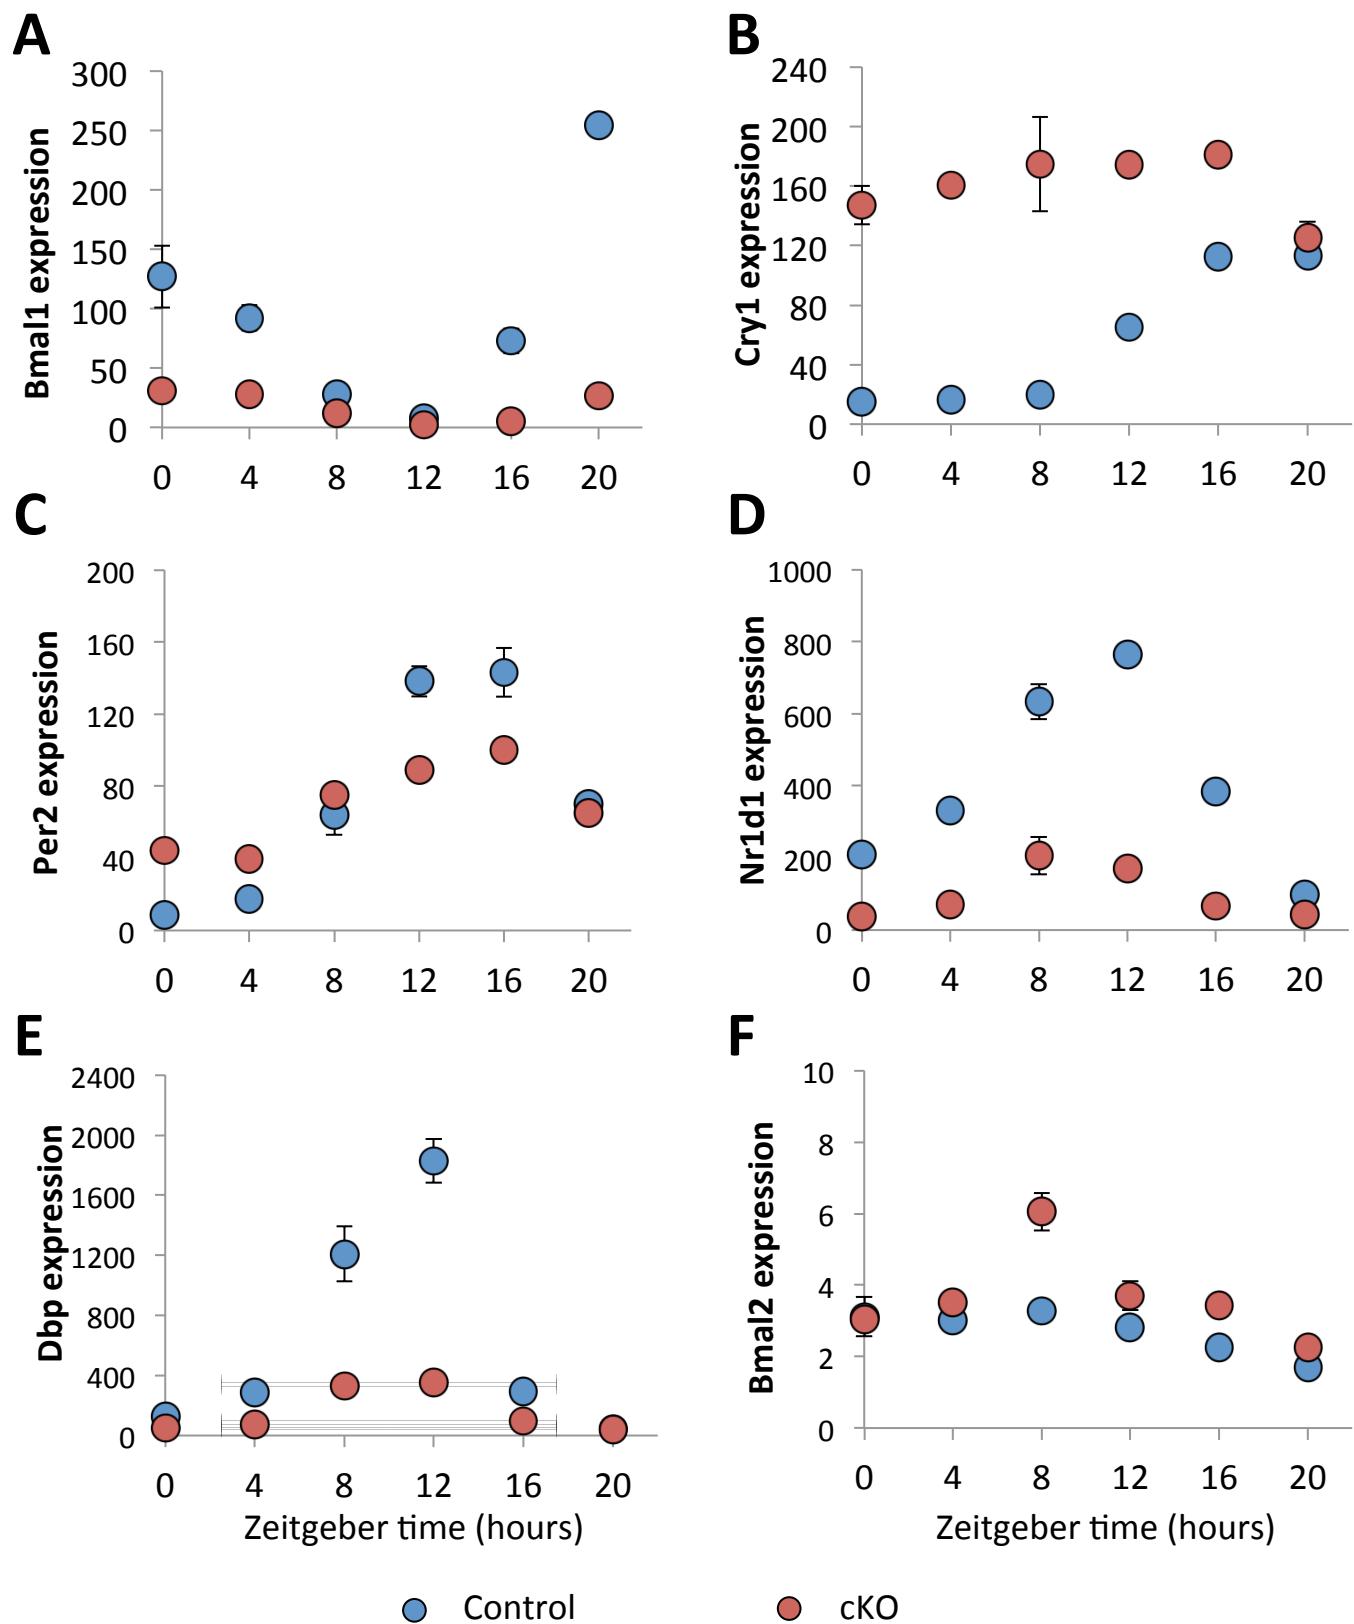

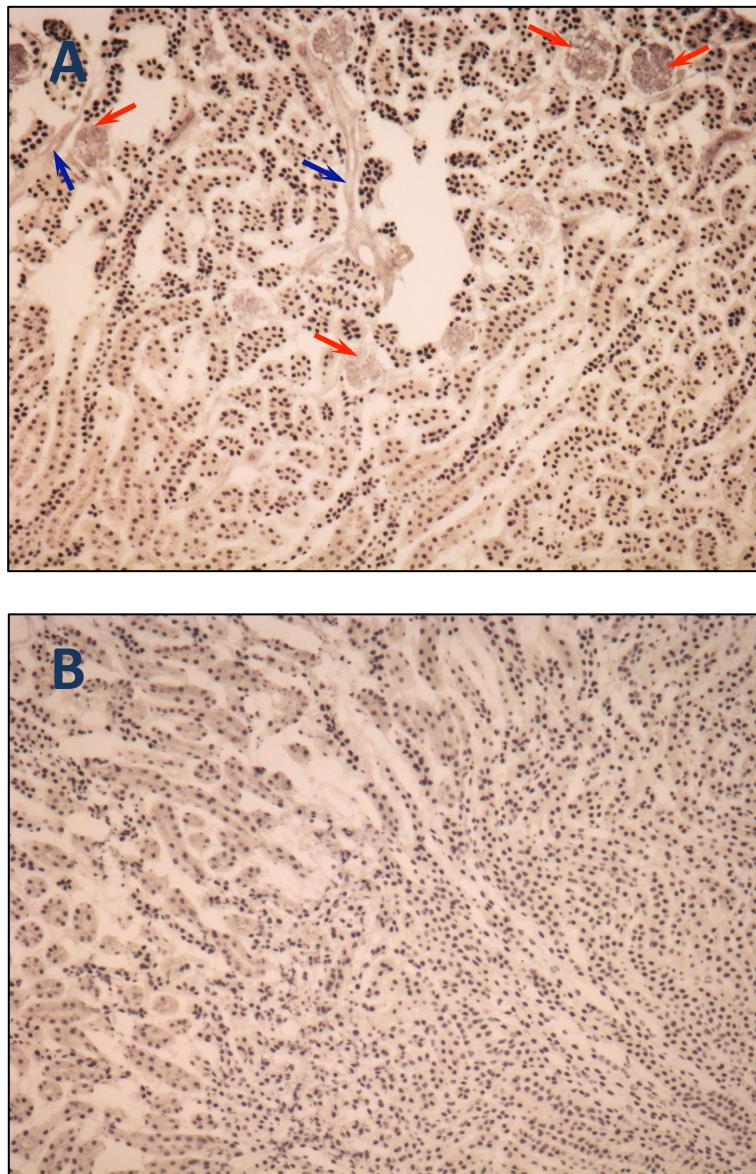

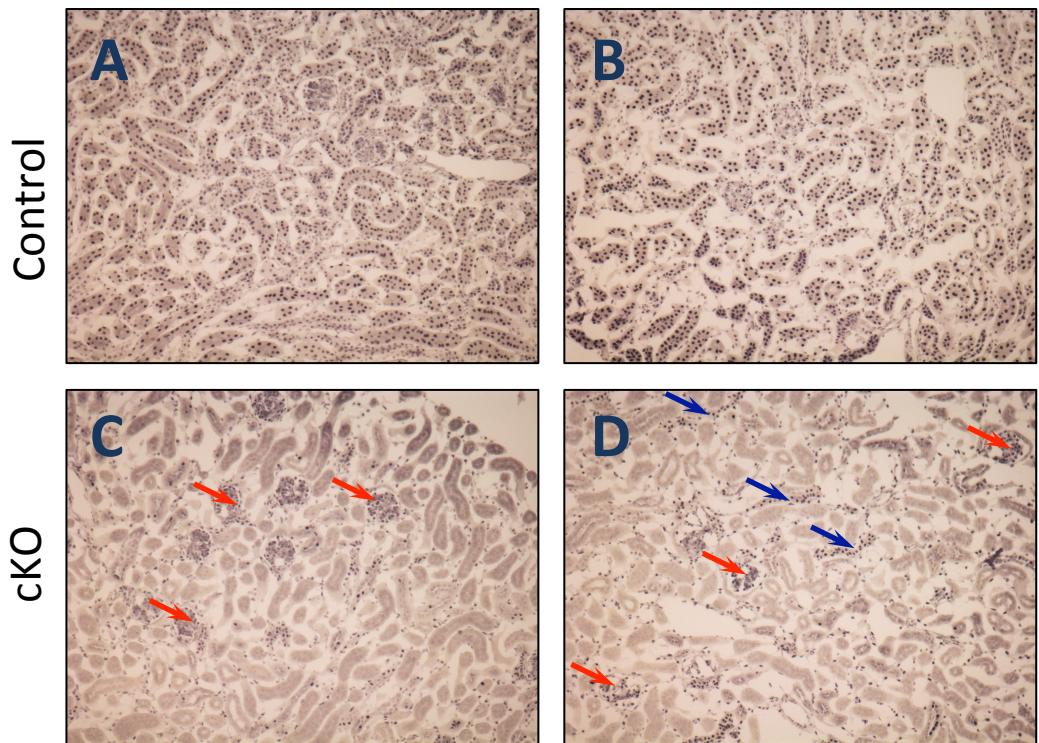

Figure 4, Nikolaeva et al.

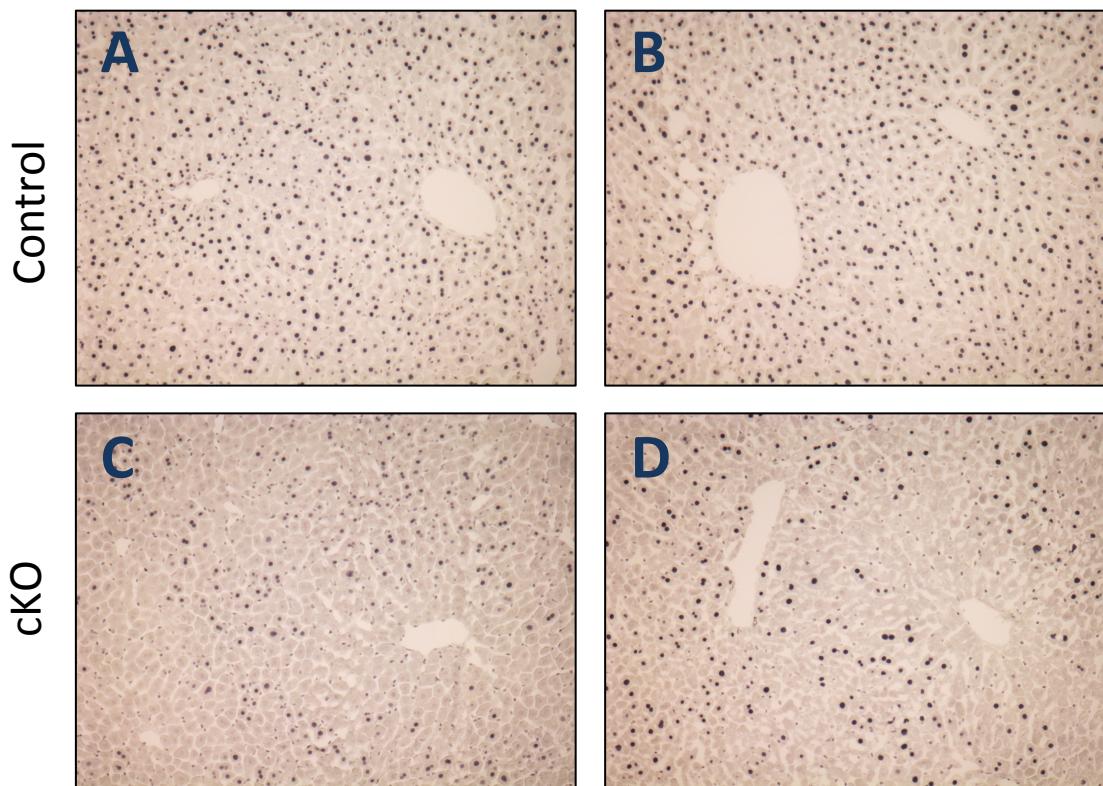

Supplemental Figure 1. qPCR analysis of Bmal1 (A), Cry1 (B), Per2 (C), Nr1d1 (D), Dbp (E) and Bmal2 (F) mRNA expression in kidneys of Control and cKO mice. n=6 for both genotypes. Error bars represent SEM. Data are expressed in arbitrary units and are standardized to Dbp expression levels in kidneys of Control animals at ZT0.

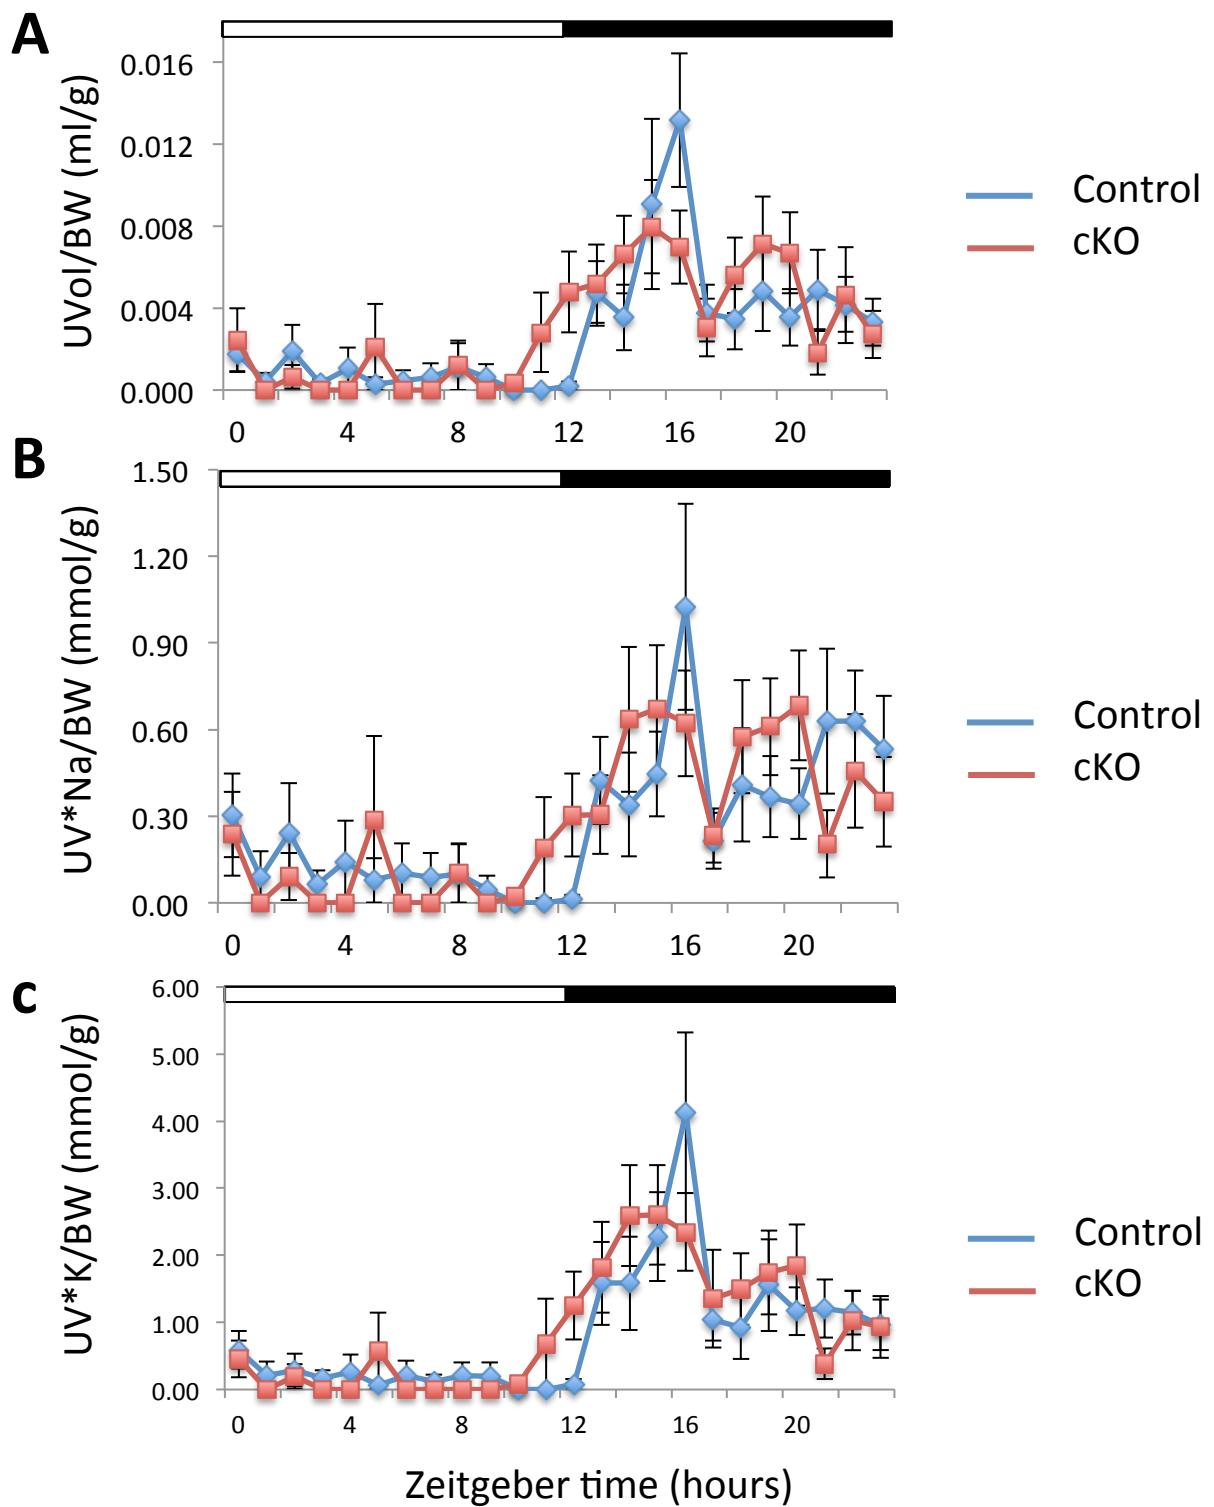

Supplemental Figure 2. Immunohistochemical localization of CRE recombinase in kidney cortex (**A**) and medulla (**B**) of cKO mice treated 5 days with DOX (2 mg/ml in drinking water). The anti-CRE recombinase antibody was from Novagen. These images show that the CRE is ubiquitously expressed in the nuclei of all renal tubular cells but not in glomeruli (red arrow) or blood vessels (blue arrow).

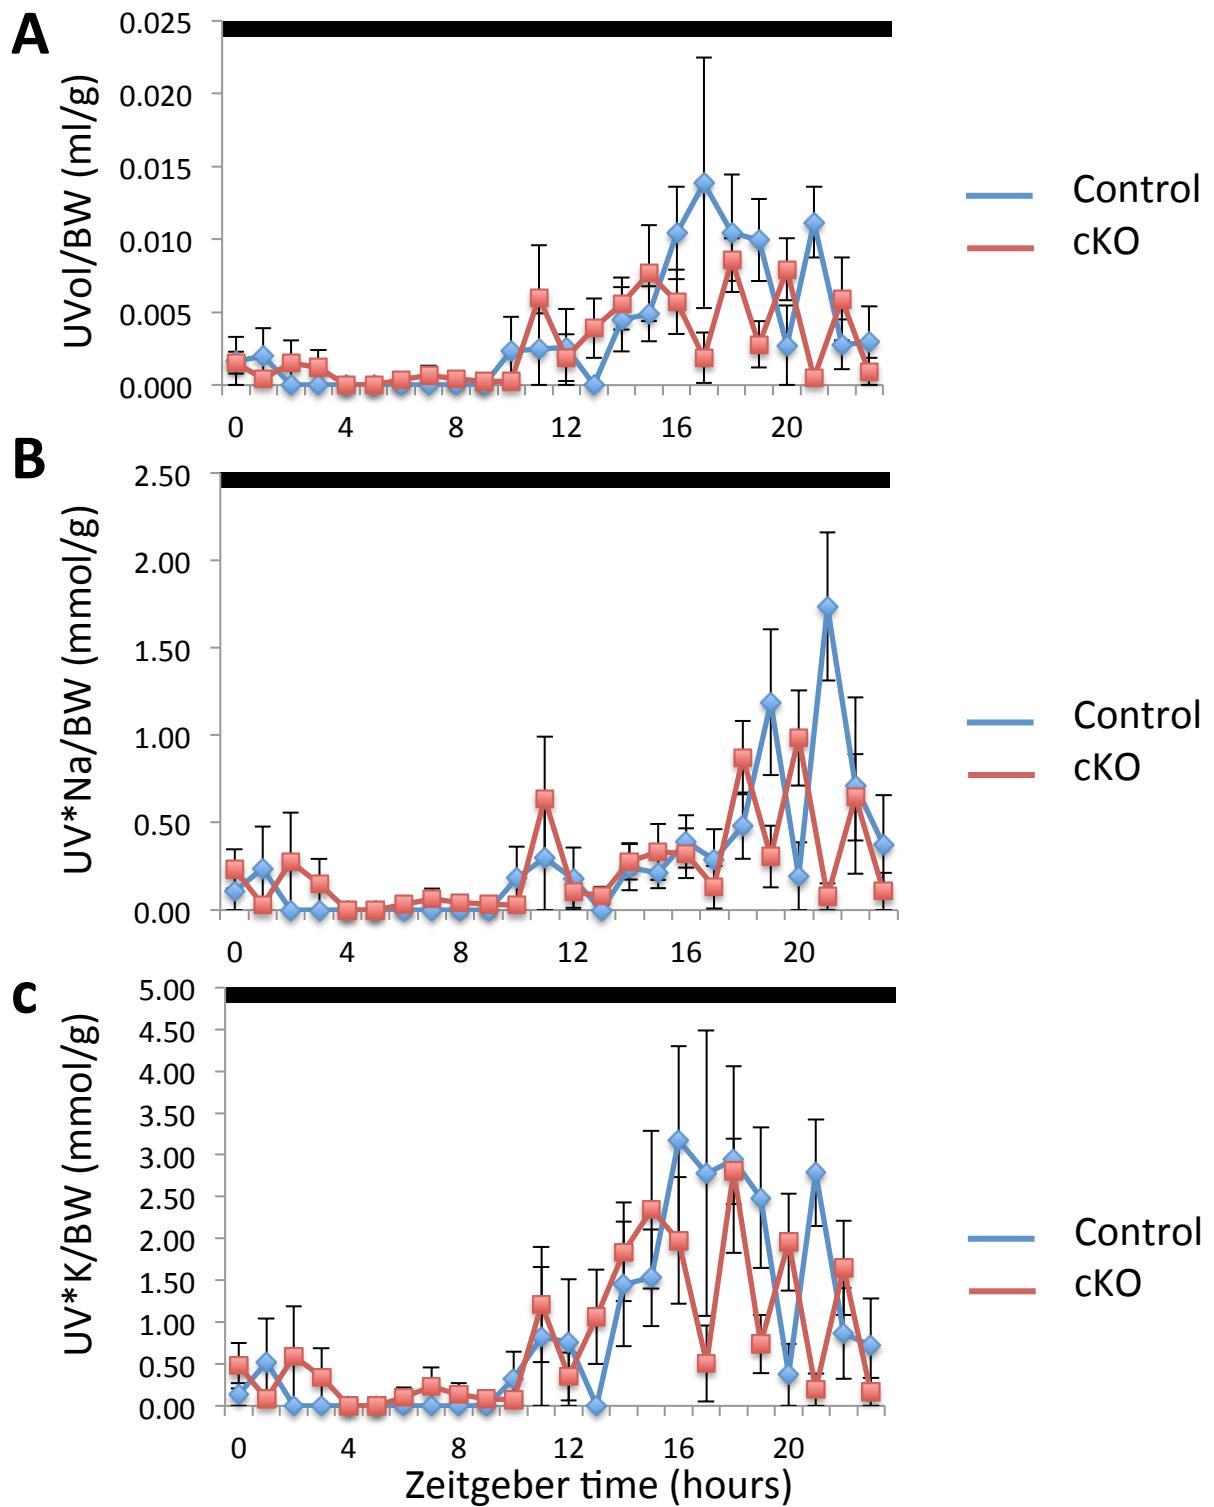

Supplemental Figure 3. Immunohistochemical localization of BMAL1 in kidney cortex of Control or cKO mice treated with DOX (2 mg/ml in drinking water). **(A)** Control mice treated 5 days with DOX. **(B)** Control mice 2 months after the end of DOX treatment. **(C)** cKO mice treated 5 days with DOX. **(D)** cKO mice 2 months after the end of DOX treatment. The anti-BMAL1 antibody was described elsewhere (12). These images show ubiquitous nuclear BMAL1 staining in kidneys of Control mice. In cKO mice, the BMAL1 expression disappeared all along the renal tubule but not in glomeruli (red arrow) or blood vessels (blue arrow).

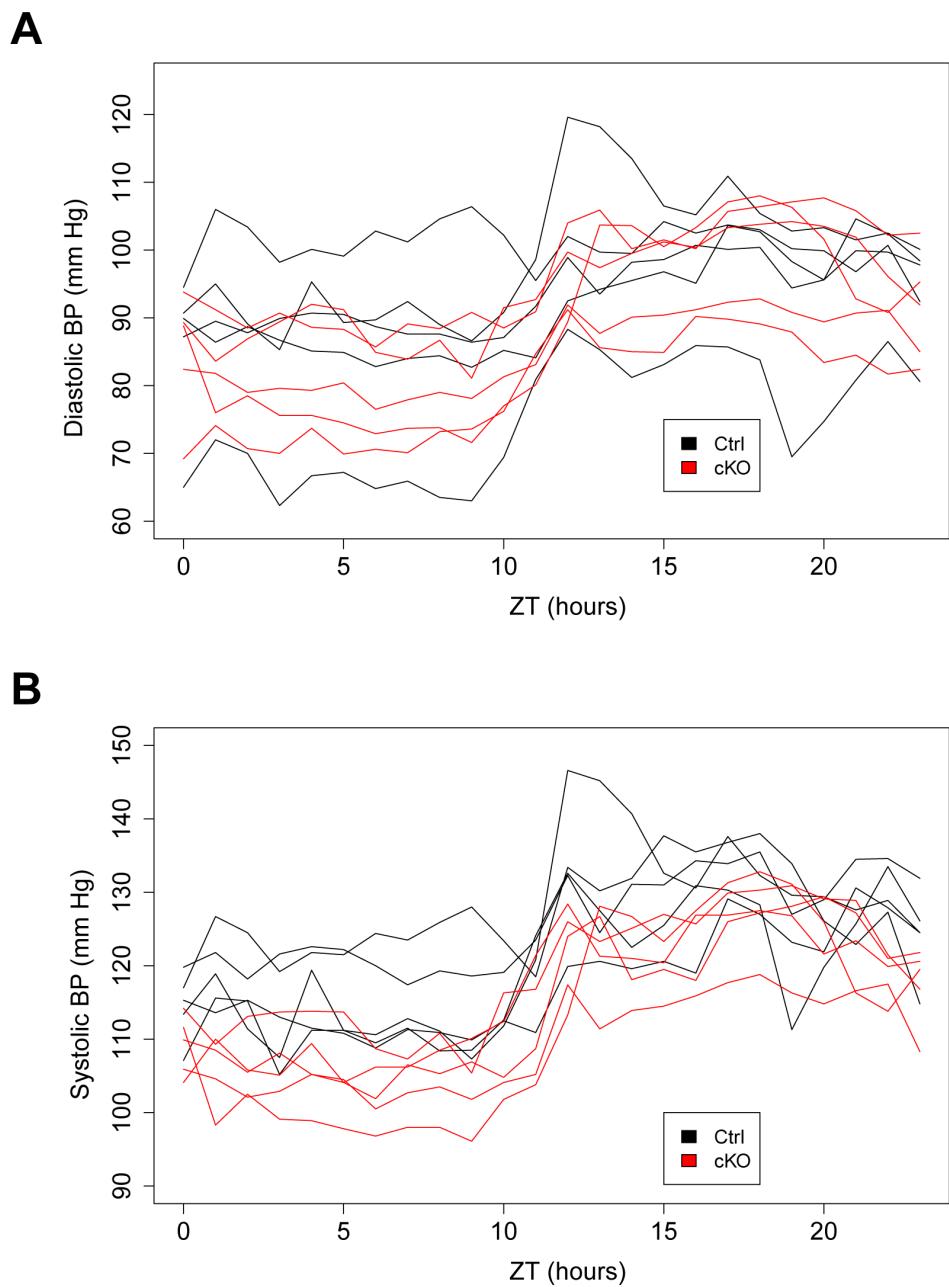

Supplemental Figure 4. Immunohistochemical localization of BMAL1 in the liver of Control or cKO mice treated with DOX (2 mg/ml in drinking water). **(A)** Control mice treated 5 days with DOX. **(B)** Control mice 2 months after the end of DOX treatment. **(C)** cKO mice treated 5 days with DOX. **(D)** cKO mice 2 months after the end of DOX treatment. The anti-BMAL1 antibody was described elsewhere (12). These images show that BMAL1 is inactivated in some proportion of liver cells located in the vicinity of the large blood vessels.

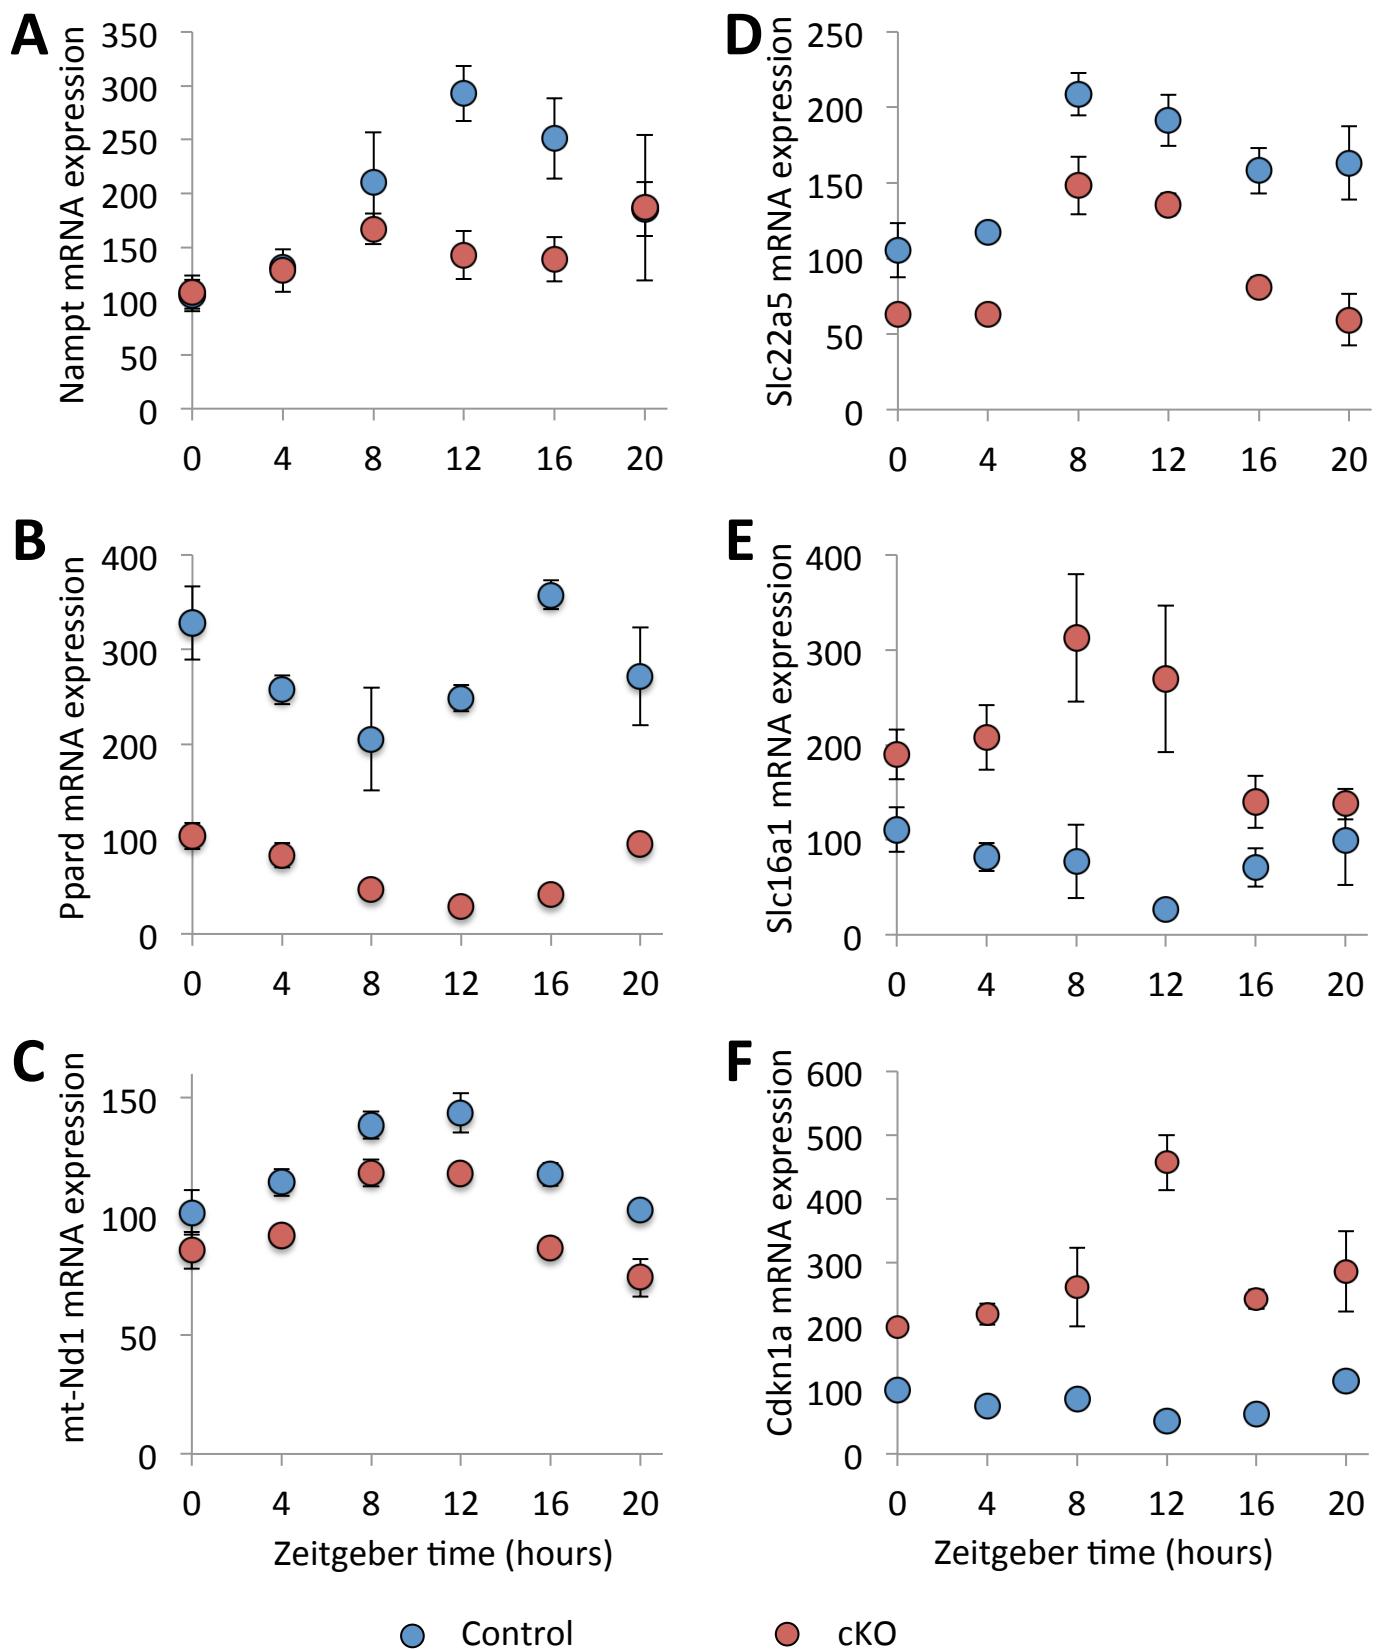

Supplemental Figure 5. Circadian patterns of renal water (**A**), sodium (**B**) and potassium (**C**) excretion in Control (blue line) and cKO mice (red line) in **light/dark** conditions. The hourly urine collection was performed in metabolic cages. The experiment was performed on Control and cKO mice 2 months after the end of DOX treatment. Two way ANOVA did not reveal the effect of genotype (Control vs. cKO: P=0.63 for water, P=0.99 for sodium and P=0.57 for potassium). n=12 for both genotypes. Error bars represent SEM.

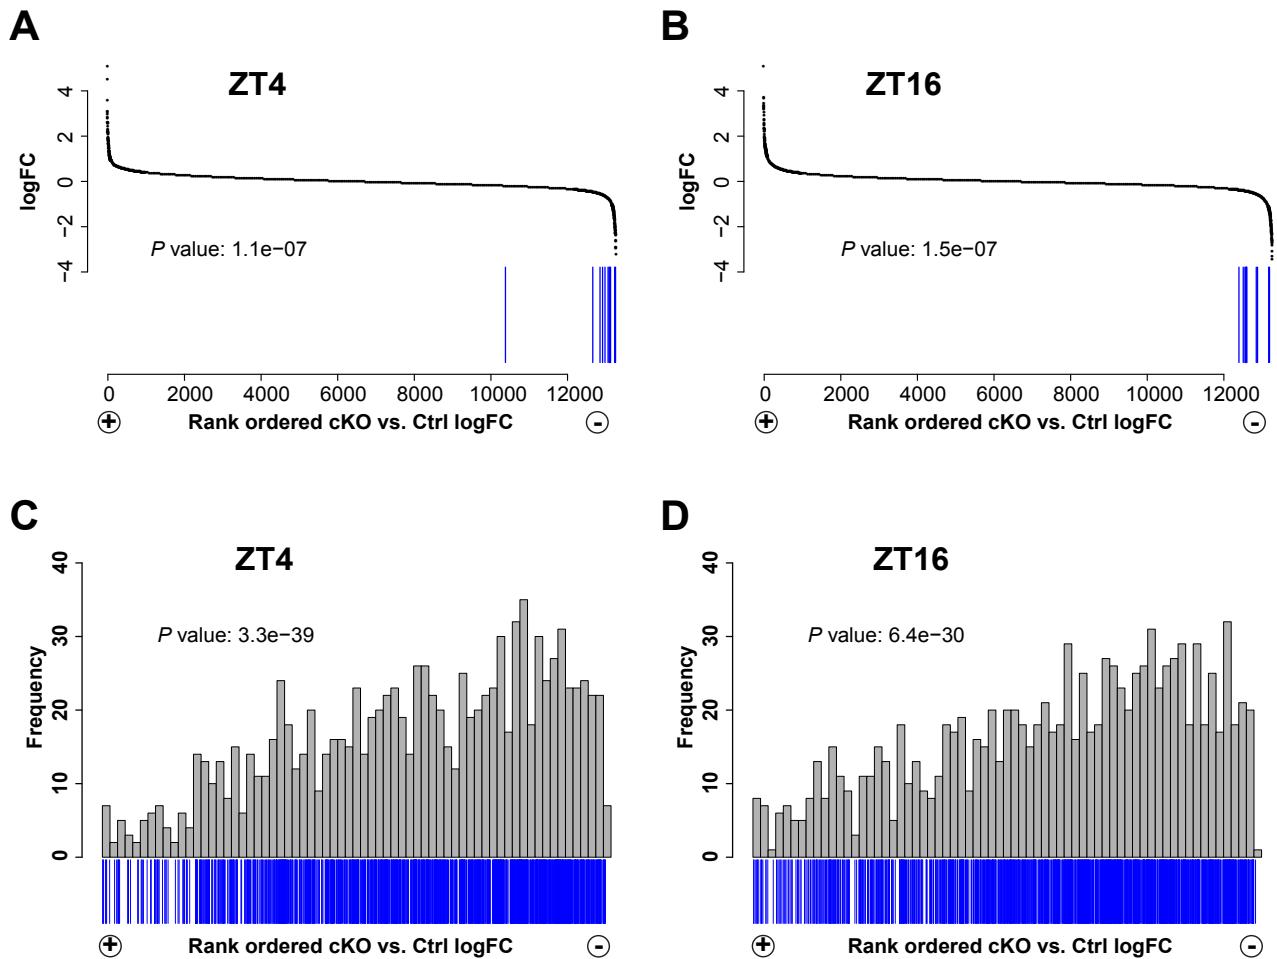

Supplemental Figure 6. Circadian patterns of renal water (A), sodium (B) and potassium (C) excretion in Control (blue line) and cKO mice (red line) in **dark/dark** conditions. The hourly urine collection was performed in metabolic cages. The experiment was performed on Control and cKO mice 2 months after the end of DOX treatment. Animals were placed in constant darkness 30 hours before urine collection . Two way ANOVA did not reveal the effect of genotype (Control vs. cKO: P=0.23 for water, P=0.45 for sodium and P=0.50 for potassium). n=6 for both genotypes. Error bars represent SEM.

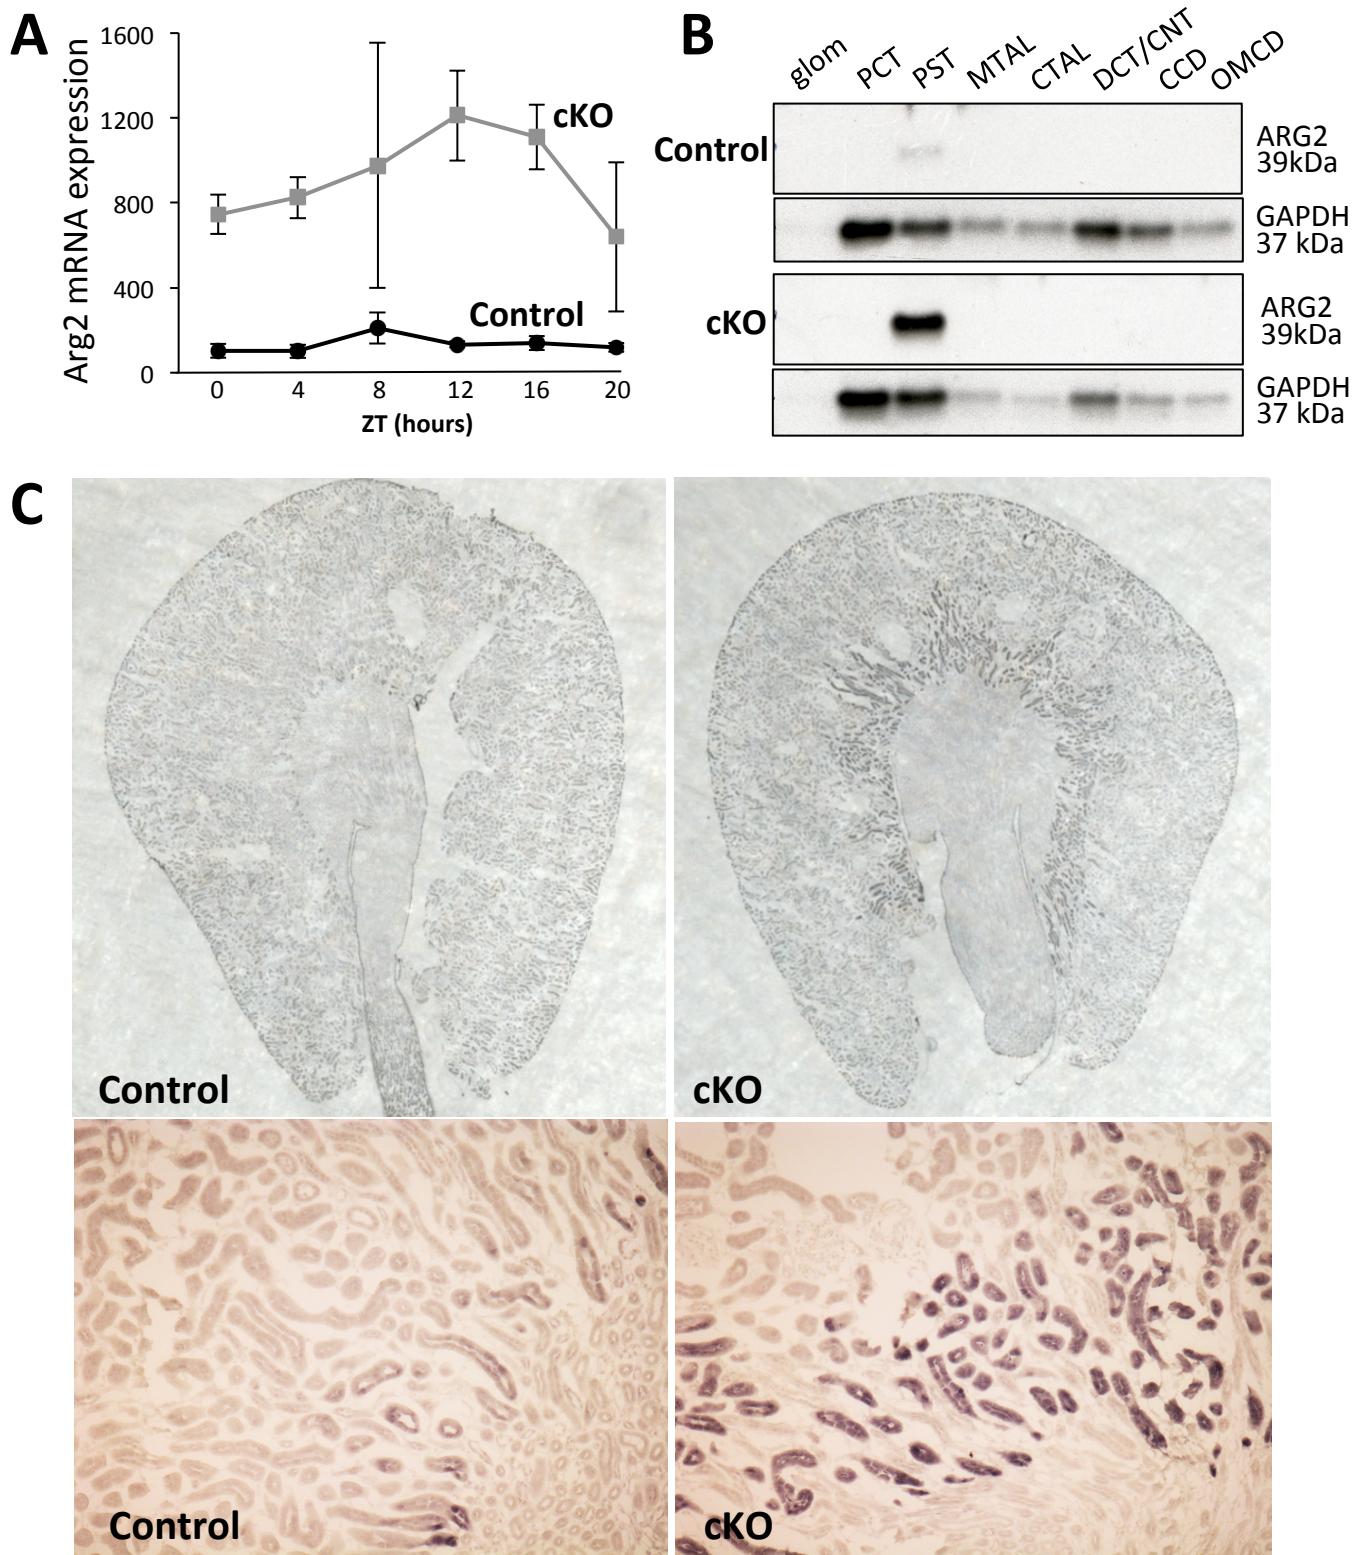

Supplemental Figure 7. Telemetry records of (A) Diastolic and (B) systolic BP from 5 Control and 5 cKO mice. For each mouse, each record represent a mean of 7-day recordings. See statistical treatment of the data in Table S2.

Supplemental Figure 8. qPCR analysis of Nampt (A), Ppard (B), mt-Nd1 (C), Slc22a5 (D), Slc16a1 (E) and Cdkn1a (F) mRNA expression in kidneys od Control and cKO mice. n=6 for both genotypes. Error bars represent SEM.

Supplemental Figure 9. Protein coding genes with at least 1 count per million in at least one sample were ordered by their log fold-change (logFC) of the difference between Control and cKO animals at ZT4 (A,C) or ZT16 (B,D) from the highest logFC on the left to the lowest logFC on the right. (A-B) Ordered logFC values (black dots) with positions of the mitochondrial DNA (mt-DNA) genes in the rank indicated by the blue tick marks. (C-D) The logFC ordered genes were binned into 50 bins. For each time point, the histogram displays the number of nuclear genes with mitochondrial localization (mt-localized) in each bin. The 1158 nuclear genes with mitochondrial localization were obtained from MitoCarta (<http://www.broadinstitute.org/scientific-community/science/programs/metabolic-disease-program/mitocarta/mitocarta-inv>). We tested the assumption that mt-DNA (A-B) or mt-localized (C-D) genes were uniformly distributed along the logFC ordered genes using a two-tailed Mann-Whitney U test. The assumption of uniform distribution was rejected, indicating an overrepresentation of mt-DNA and mt-localized genes among down-regulated genes in Bmal1 KO.

Supplemental Figure 10. Arginase 2 expression in kidneys of Control and cKO mice. **A.** Circadian pattern of Arg2 mRNA expression in kidneys of Control and cKO mice.

Arbitrary units, Arg2 mRNA levels in kidneys of Control mice at ZT0 were considered as 100%. Mean \pm SD, n=6. **B.** ARG2 Western probing performed on microdissected tubular segments (10 mm/segment) or 10 glomeruli. **C.** Immunohistochemical ARG2 localization in kidneys of Control and cKO mice.

Supplemental Methods.

Gene expression analysis by RNASeq RNA-seq libraries were prepared using 500 ng of total RNA and the Illumina TruSeq Stranded mRNA reagents (Illumina; San Diego, California, USA) on a Caliper Sciclone liquid handling robot (PerkinElmer; Waltham, Massachusetts, USA) using a Caliper-developed automated script. Cluster generation was performed with the resulting libraries using the Illumina HiSeq PE Cluster Kit v3 reagents and sequenced on the Illumina HiSeq 2500 using HiSeq SBS Kit v3 reagents. Sequencing data were processed using the Illumina Pipeline Software version 1.82. Purity-filtered reads were adapters and quality trimmed with Cutadapt (v. 1.3.) and filtered for low complexity with PRINSEQ (v. 0.20.3.) (1). Reads were aligned against *Mus musculus* GRCh38 genome using Tophat (v. 2.0.9) (2). Quality of the RNASeq data alignment was assessed using RSeQC (v. 2.3.7, RSeQC (v. 2.3.7, (3)). The number of read counts per gene locus was summarized with htseq-count (v. 0.6.1) using *Mus musculus* GRCh38.75 gene annotation (4). Data was further processed in R (v. 3.1.2), using Bioconductor packages. The 13,279 protein coding genes with at least 1 count per million in at least one sample were normalized with scaling factors computed by the TMM method (Bioconductor package *edgeR*, (5)) and subsequently transformed to log2-counts per million by voom, a method implemented in the R Bioconductor package *limma* (6). Differences in gene expression levels between KO and WT animals at ZT4 and ZT16 were combined into one F-test using the *limma* package (7). Statistically significant genes (False Discovery Rate < 5%) were classified for being affected at ZT4, ZT16 or at both time points using the nestedF method from *limma*. Gene Ontology (GO) analysis was performed using GOrilla using all protein coding genes from *Mus musculus* GRCh38.75 as background list (8). Significant enriched biological processes GO terms were identified after Bonferroni correction (P value < 3.68e-06). GO terms that were not at least 4 levels above the root node were discarded (generic terms). Enriched GO terms

representation was generated using REVIGO (9). The complete data set is publicly available at GEO through the accession number GSE76838.

NOS activity Mouse kidneys were homogenized in 10 volumes (w/v) of solution containing 250 mM sucrose, 1 mM EDTA and protease inhibitors cocktail (Roche), pH 7.7. The homogenate was centrifuged at 14000 rpm, +4°C, 20 min. The supernatant was collected and 5 ml were incubated in 50 ml of reaction mixture containing 2 mM CaCl₂, 1 mM NADPH, 25 µM FAD, 1.25 µg/ml calmodulin, 10 µM BH₄, and 0.5 µl of [¹⁴C]-L-Arginine (100 µCi/ml), 20 mM HEPES, pH 7.2, 1h at 37°C (10). The reaction was stopped by adding of 200 µl acetone. The samples were incubated overnight at -20°C for protein precipitation. The proteins were removed by centrifugation at 14000 rpm, +4°C for 20 min. The supernatants were collected and dried in vacuum. The dried samples were dissolved in 25 µl methanol:water (2:1, v/v) (11). 5 µl of dissolved samples were applied to silica gel TLC plates (Sigma) along with L-citrulline and L-arginine standards, and TLC was performed in C₂H₅OH : 25% NH₄OH (2:3, v/v). The standards spots were visualized after treatment the silica gel with 0.25% ninhydrin prepared in acetone, the plate areas corresponding to L-citrulline were processed for the determination of radioactivity. NOS-specific L-citrulline formation was determined as the difference between samples containing 2 mM L-NAME and samples without L-NAME.

Time	1	250656	250656	14.6282	0.00106 **
Genotype*Time	1	1166	1166	0.0681	0.79685

2-way ANOVA was performed with genotype (Control, *cKO*), time (ZT4 and ZT16) and interaction between time and genotype as factors.

P values are indicated in figure legends. A P value less than 0.05 was considered significant.

Supplemental Table 2. Diastolic (A) and Systolic (B) BP in Control and cKO mice n = analysis of

variance A. Diastolic Blood Pressure light phase vs. dark phase

Factor	Df	Sum Sq	Mean Sq	F value	Pr(>F)
Genotype	1	52.62	52.62	2.8803	0.1281067
Time	1	806.77	806.77	44.1576	0.0001616
Animal	8	1229.82	153.73	8.4141	0.0034175
Genotype*Time	1	23.93	23.93	1.3096	0.2855575
Residuals	8	146.16	18.27		

B. Systolic Blood Pressure light phase vs. dark phase

Factor	Df	Sum Sq	Mean Sq	F value	Pr(>F)
Genotype	1	336	336	29.8249	6.01E-04
Time	1	1105.71	1105.71	98.1493	9.10E-06
Animal	8	242.27	30.28	2.6881	0.0917283
Genotype*Time	1	13.68	13.68	1.2144	0.3025017
Residuals	8	90.12	11.27		

ANOVA were performed with genotype (Control, cKO), time (light phase vs. dark phase), mouse (for mouse to mouse variability) and interaction between time and genotype as factors.

Supplemental Table 3: Quantity of RNAN seq reads generated and aligned against Mus musculus GRCh38 genome

RNA sample	CtrlZT16_1	CtrlZT16_3	CtrlZT16_5	CtrlZT4_1	CtrlZT4_3	CtrlZT4_5
