Selective Incivility: Immigrant Groups Experience Subtle Workplace Discrimination at Different Rates

Franciska Krings and Claire Johnston

Immigrants play an increasingly important role in local labor markets. Not only do they grow steadily in number but also in cultural, educational, and skill diversity, underlining the necessity to distinguish between immigrant groups when studying discrimination against immigrants. We examined immigrant employees’ subtle discrimination experiences in a representative sample in Switzerland, controlling for dispositional influences. Results showed that mainly members of highly competitive immigrant groups, from immediate neighbor countries, experienced workplace incivility and that these incivility experiences were related to higher likelihoods of perceived discrimination at work. This research confirms recent accounts that successful but disliked groups are particularly likely to experience subtle interpersonal discrimination.

Keywords: discrimination, incivility, immigrants, diversity

During the last decade, immigrants accounted for 70% of the increase of the workforce in Europe and for 47% in the United States (OECD, 2012a). Currently, they make up 16% of the workforce in the United States, 21% in Canada, and 27% in Switzerland, that is, the country where the present study was conducted (OECD, 2012b; Swiss Federal Statistics Office [SFSO], 2012). Immigrants have not only increased in number but also in cultural, educational, and skill diversity. For example, in 2000, most immigrants to the United States came from Hispanic countries, while in 2012 most immigrants came from Asia (Pew Research Center, 2012). Similarly, most of the earlier immigrants to Switzerland came from Southern Europe while today most immigrants come from Western European neighbor countries (Liebig, Kohls, & Krause, 2012). These new immigrants have higher education levels and work in higher-status positions than earlier immigrants, responding to many nations’ increasing demand for highly skilled labor.

In research on workplace discrimination, immigrants have received little attention (Binggeli, Dietz, & Krings, 2013). However, theories of prejudice and discrimination suggest that immigrants are likely targets of subtle forms of prejudice and discriminatory behaviors. Subtle, interpersonal discriminatory behaviors particularly target members of groups perceived as competent competitors (Cortina, 2008; Fiske, Cuddy, Glick, & Xu, 2002). Hence, members of recent, highly skilled immigrant groups may experience more subtle discrimination than members of earlier, less skilled immigrant groups.

This was the starting point of the present research. It studied the experience of subtle workplace discrimination of immigrants and locals in a representative sample of employees in Switzerland. We focused on the experience of incivility, that is, of being the target of low-intensity discourteous interpersonal behaviors (Andersson & Pearson, 1999). Incivilities are general but if they selectively target a minority group, grounded in diffuse antiminority feelings and stereotypes, they become a form of subtle interpersonal discrimination (Cortina, 2008). Because immigrants are targets of subtle prejudice and mainly associated with mixed, ambivalent stereotypes (Lee & Fiske, 2006; Pettigrew & Meertens, 1995), we expected immigrants to experience more incivility than locals. Further, theories of intergroup competition and stereotype content suggest that groups perceived as competitive and highly competent but as little likable, experience more subtle discrimination (Esses, Dovidio, Jackson, & Armstrong, 2001; Fiske et al., 2002). Indeed, depending on their national origin, immigrant groups differ remarkably on perceived competence and likability (Lee & Fiske, 2006). Hence, we expected immigrants belonging to groups perceived as highly competent but less likable to be particularly frequent targets of incivility. Of importance, these differences are
Selective Incivility as Subtle Discrimination Against Immigrants

At the base of subtle discrimination are subtle prejudice and stereotypes (Cortina, 2008; Dipboye & Halverson, 2004). Subtle prejudices encompass the belief that discrimination is a thing of the past, that minority groups’ claims are unfair and that there are large (cultural) differences between social groups (Gaertner & Dovidio, 1986; McConahay, 1986; Swim, Aikin, Hall, & Hunter, 1995). These beliefs present a subtle, ostensibly rational form of expressing prejudice and help people preserve a nonprejudiced self-image. In a similar vein, recent work on the content of stereotypes has shown that most group stereotypes are mixed, that is, contain positive (e.g., trustworthy) and negative (e.g., incompetent) elements (Fiske et al., 2002). Because of the positive elements, many stereotypical beliefs are subjectively experienced as nonprejudicial (Glick & Fiske, 1996, 2001). Subtle prejudices and mixed stereotypes result in interpersonal rather than in formal discrimination (Hebl, Foster, Mannix, & Dovidio, 2002). Interpersonal discrimination emerges in social interactions at work, including verbal, nonverbal, and paraverbal behaviors, and is subtler and more compatible with a nonprejudiced self-image than formal, more direct discrimination, which occurs, for example, at hiring or promotion and is, in most countries, against the law.

Cortina (2008) recently proposed that workplace incivility may take the form of subtle, interpersonal discrimination. Incivility is “low-intensity deviant behavior with ambiguous intent to harm the target, in violation of workplace norms for mutual respect. Uncivil behaviors are characteristically rude and discourteous, displaying a lack of regard for others” (Andersson & Pearson, 1999, p. 457). It encompasses behaviors such as interrupting, ignoring or using a condescending tone. Despite their low-intensity, these behaviors have several detrimental consequences for targets, such as greater levels of stress, lower commitment and job satisfaction, or higher quit rates (Pearson & Porath, 2004).

When incivility selectively targets members of minority groups, based on ambivalent antiminority feelings and stereotypes, it becomes discrimination (Cortina, 2008). This discrimination is subtle because of the ambiguous nature and apparent neutrality of the uncivil behaviors, instigators easily find (consciously or not) non-prejudicial explanations for their conduct (e.g., “I have too much work”). Selective incivility is hence a particularly well-suited means by which people may mistreat minorities without damaging their nonprejudiced image of themselves and toward others.

Recent studies provide first empirical evidence for such targeted incivilities: Men and Whites (Cortina et al., 2002; Cortina, Kabat-Farr, Leskinen, Huerta, & Magley, 2011). In this research, we examined incidence rates of incivility for immigrants, compared with locals. Several elements suggest that immigrants are likely targets. First, immigrants are targets of subtle prejudice (Akrami, Ekehammar, & Araya, 2000; Pettigrew & Meertens, 1995). Further, immigrants are mainly associated with ambivalent or mixed stereotypes, which encompass positive and negative features: Most immigrant groups are either perceived as incompetent but nice (e.g., Irish immigrants in the United States or Portuguese immigrants in Switzerland) or as competent but less likable (e.g., Asian immigrmigrants in the United States or German immigrants in Switzerland) (Binggeli, Krings, & Szczesny, in press; Lee & Fiske, 2006). Subtle prejudice toward immigrants and mixed immigrant stereotypes provide the attitudinal and cognitive basis for subtle mistreatments at work. Second, earlier research on employment discrimination has shown that subtle prejudice indeed fosters discrimination against immigrants (Krings & Oliwares, 2007; Petersen & Dietz, 2005). Finally, immigrants themselves report feeling discriminated against at work (Jasinskaja-Lahti, Liebkind, & Perhoniemi, 2007; Kravitz & Klineberg, 2000).

Therefore, we expected the following:

Hypothesis 1: Immigrants report more experiences of workplace incivility than locals.

When analyzing differences between social groups, it is important to control for personality differences because certain characteristics of the target may contribute to the likelihood of experiencing discriminatory behaviors (Milam, Spitzmueller, & Penney, 2009). For example, people low in agreeableness or high in neuroticism tend to be distrustful and display discourteous, bother-some behaviors (McCrae & Costa, 1987). Thus, they may be more likely to perceive an event as rude, as well as to provoke uncivil behaviors from others as a reaction to their own behaviors. Indeed, people low in agreeableness and high in neuroticism experience more incivility (Milam et al., 2009). As a consequence, for testing our hypotheses, we controlled for employees’ level of neuroticism and agreeableness, to assure that effects of group membership would persist, above and beyond those of individual differences.

Some Immigrant Groups Are More Likely Targets of Incivility Than Others

The global stereotype of immigrants as a group is that they are untrustworthy and incompetent (Eckes, 2002). However, recent work suggests that immigrants should not be treated as one entity: Stereotypes of immigrants differ remarkably between groups depending on the group’s country of origin. Drawing on the stereotype content model, Lee and Fiske (2006) showed that perceptions of warmth (being good-natured, kind) and competence (being intelligent, skillful) of immigrant groups differed as a function of the groups’ national origin. These perceptions result from socio-structural relations between locals and immigrant groups: Immigrant groups viewed as high status are perceived as high in competence and groups viewed as competing for resources are perceived as lacking warmth.

Importantly, different warmth and competence stereotypes give rise to more or less hostile behaviors (Cuddy, Fiske, & Glick, 2007; Sibley, 2011). As outlined above, mixed stereotypes provide the foundation for subtle behaviors undermining equality. Hence, most immigrants should be likely targets of subtle mistreatments at work. However, groups perceived as competent but cold should be somewhat more targeted than groups perceived as incompetent but...
nice because the former elicit more hostility, especially when they gain more status or power (e.g., when they are successful in the labor market) than the latter (Cuddy, Fiske, & Glick, 2008; Fiske et al., 2002). The clear competence and ability of these groups makes it difficult to blatantly discriminate against them. However, their perceived lack of interpersonal warmth and sociability makes it easier to subtly discriminate against them, in everyday social interactions at work (e.g., by addressing them in unprofessional terms). Similarly, Cortina (2008) argued that professionally successful women and black professionals are particularly prone to experience selective incivility because they are considered (excessively) competent and ambitious, ultimately threatening the dominant position of the majority.

These considerations suggest that immigrants belonging to national or ethnic groups perceived as competent but cold are more likely targets of workplace incivility. In Switzerland, it is immigrants from the immediate neighbor countries (Germany and France) that receive this stereotype. These immigrants are perceived as highly competent but less likable, as demonstrated by a recent analysis of warmth and competence stereotypes of the most salient immigrant groups in Switzerland (Binggeli et al., in press). Four groups emerged from this analysis: (1) immigrants perceived as low in competence and low in warmth, comprising immigrants from the Balkans, Turkey, and Eastern Europe; (2) immigrants perceived as moderately warm but incompetent, with immigrants from Africa; (3) immigrants perceived as highly warm but moderately competent, comprising immigrants from Southern Europe; and, finally, (4) immigrants perceived as highly competent but lacking warmth, consisting of German and French immigrants. Warmth perceptions of German immigrants were particularly low in the German-speaking region of Switzerland, whereas warmth perceptions of French immigrants were particularly low in the French-speaking region.

The number of German and French immigrants has multiplied since Switzerland introduced freedom of movement for people from European-Union member states in 2002 (Liebig et al., 2012). Since then, no other immigrant group has increased in size as considerably and as rapidly as they have. Today, these immigrants are among the three largest immigrant groups in Switzerland. Compared with immigrants from other nations, they have a strong competitive advantage: They speak one of the two main national languages of Switzerland (i.e., German or French) and tend to be highly educated. Hence, it is no surprise that they have higher employment rates and are more likely to work in high status positions than any other immigrant group, and even than locals (SFSO, 2012). The competitiveness of these groups has led to a heated public debate, revealing that they are perceived as a threat and strong competitors for desirable resources such as jobs. Indeed, the perceived competitiveness of these groups explains their low levels of likability or perceived warmth (Binggeli, Krihs, & Sczesny, 2013). Taken together, in certain ways, German and French immigrants are comparable with Asians in the United States, which is a group that too is very successful on the labor market and that too is stereotyped as excessively competitive and highly competent, but as lacking sociability (Lee & Fiske, 2006; Lin, Kwang, Cheung, & Fiske, 2005).

In summary, based on German and French immigrants’ high-competence or low-warmth stereotype as well as their strong competitiveness, we expected the following:

**Hypothesis 2:** Immigrants from France and Germany report more experiences of workplace incivility than immigrants of other nations, so that German and French immigrants report the highest rate of incivility, followed by other immigrants, followed by locals.

**Linking Selective Incivility and Perceived Discrimination**

To what extent incivility experiences fuel perceptions of discrimination by the target is an open question. On the one hand, given the apparently neutral and ambiguous nature of incivility, it may be difficult for targets to recognize it as discrimination (Cortina, 2008). Targets may be just as ready to find nonprejudicial explanations for receiving uncivil treatment as instigators do for acting uncivil. On the other hand, over time, targets may realize that they are mistreated more frequently than their colleagues and come to realize that being the target is related their minority status. Moreover, if incivility selectively targets their group, they are likely to observe that other members of their group are treated similarly, further highlighting the discriminatory component and increasing the probability of feeling discriminated against.

To our knowledge, the relation between selective incivility and perceived discrimination has not been empirically tested yet. In the light of the considerations above, we analyzed the relation in an exploratory manner.

**Method**

**Participants and Procedure**

This study is part of a larger, longitudinal project, hosted by the National Centre of Competence in Research LIVES. Data for this study are from the first data collection wave in 2012. A representative sample of the working age population living in Switzerland was drawn based on a random sample from the Swiss Federal Statistics Office. Sampling was targeted at the two largest linguistic regions, the German-speaking and the French-speaking regions, and was representative in terms of age, gender, linguistic region, and nationality.

Participants (n = 2,001) completed a research protocol consisting of two steps. The first part, completed by a computer-assisted telephone interview or as an online questionnaire, aimed to explain the goal of the study, verify the inclusion criteria (e.g., age between 25 and 55, living in Switzerland) and determine the participants’ professional situation and biography. The second part, completed via a paper-pencil or as an online questionnaire, assessed aspects of the work and social environment, personal characteristics and general outcomes. Most participants (79%) completed both parts online. Most of the local and immigrant participants (67%) answered the questionnaire in German. This proportion corresponds to the percentage of people living in the German part, that is, in Switzerland’s largest linguistic region.

The University of Lausanne does not have an institutional review board for psychology or social science research. This research thus applied the ethical standards of the Swiss Psychological Society. Accordingly, the survey avoided any treatment that might have a detrimental effect on the well-being or integrity of participants. During the first part, participants were informed...
about the purpose of the study and were ensured their data would remain confidential. Agreement to participate by responding to the questions and filling out the questionnaire was taken as consent.

For the present research, we included only employed participants. The resulting sample consisted of 1,661 employees, of which 1,359 were Swiss and 302 were immigrants. Hence, 18% of participants were immigrants. This is somewhat lower than the current percentage of immigrants in the Swiss workforce (27%) and can be explained by the study’s inclusion criteria (e.g., only workers between age 25 and 55 were included) and by the fact that participants needed sufficient proficiency in French or German to participate.

Of the immigrant participants, 43.4% came from France or Germany. The remaining immigrants, grouped into one category for the following analyses, came from various countries: 24% came from Southern European countries (e.g., Portugal, Spain), 11% from Northern European countries (e.g., Norway, Sweden), 8% from the Balkans (e.g., Bosnia, Croatia) or Turkey, 4% from countries in Eastern Europe or central Asia (e.g., Ukraine, Russia), and the rest (9.6%) from various countries in Asia, Northern or Southern America. Most (63%) had permanent residence permits, 8% from the Balkans (e.g., Bosnia, Croatia) or Turkey, 4% from Northern European countries (e.g., Norway, Sweden), 11% from Northern European countries (e.g., Portugal, Spain), half of the local (49%) and immigrant participants (48%) were women. Locals were on average 42.15 years (SD = 8.63) and immigrants 40 years (SD = 7.87) old. Mean educational levels (ranging from 1 = obligatory schooling, 4 = degree in higher education) were 2.80 (SD = 0.97) for locals and 2.90 (SD = 1.14) for immigrants. Furthermore, educational mean level comparisons suggest that immigrants from Germany and France were better educated, M = 3.31, SD = 0.91, than immigrants of other nationalities, M = 2.61, SD = 1.21, or locals. This pattern mirrors the current Swiss labor market (Liebig et al., 2012). However, these numbers should be interpreted with caution, for two reasons. First, 120 participants (95 locals and 26 immigrants) did not indicate their education. Second, participants indicated their educational level with predefined categories that are used in the Swiss education system, which can be problematic because of differences in educational systems between countries.

The majority of locals (75.5%) and immigrants (84.9%) were employed at an activity rate of 80% and more, that is, they worked between 36.2 (80%) and 42 hr (100%) per week. A bit less than half of the participants (43% and 44% of locals and immigrants, respectively) indicated holding a supervisory position. German and French immigrants were more likely to hold a supervisory position (54.2%) than immigrants of other nationalities (36.3%) or locals (43%).

### Measures

Descriptive statistics, correlations, and reliabilities (alpha coefficients) for the measures are reported in Table 1. Unless specified otherwise, a team of bilingual (French- and German-speaking) researchers translated scales that only existed in English into French and German. A second team of bilingual researchers independently verified the translations, to make sure that the German and French versions were equivalent. The entire questionnaire was pretested for comprehensibility of instructions and items in a sample of 50 adults between the ages of 25 and 55 (25 women; 25 German-speaking; 25 French-speaking).

Workplace incivility was measured with four items of the incivility measure developed by (Cortina, Magley, Williams, and Langhout, 2001; see Table 2, p.70), choosing those items that showed the highest factor loadings in the initial validation study. More specifically, participants were asked to indicate how often during the past 12 months they had been in a situation where any of their coworkers or supervisors (1) had put them down or was condescending, (2) paid little attention to their statement or little interest in their opinion, (3) made demeaning or derogatory remarks about them, or (4) addressed them in unprofessional terms, either publicly or privately. Responses were indicated on 5-point scales, ranging from 1 = never to 5 = most of the time.

Perceived discrimination was assessed with a single item, similar to the one of the Gallup Survey, analyzed by Avery, McKay and Wilson (2008). Participants were asked if they had been discriminated against, based on their ethnicity or nationality, within their workplace during the past 12 months. Responses were indicated as yes or no.

Note. Perc. discrimination = Perceived workplace discrimination based on national or ethnic origin (coded as 0 = no and 1 = yes). G/F immigrants = German or French immigrants (0 = local, 1 = German or French immigrants). Other immigrants = immigrant of nationalities other than German or French (0 = local, 1 = other immigrant). Gender was coded as 0 = male, 1 = female. Age was assessed in years. Activity rate was assessed in percentages (1 = 4% or less, 20 = 95–100%). Reliabilities are shown in parentheses along the diagonal. For all correlations n between 1,640 and 1,661.

*p < .05. **p < .01.
Control variables related to participants’ personality, demographics, and work context were used to isolate the effects of immigrant status and nationality on incivility. First, we controlled for participant agreeableness and neuroticism because people low in agreeableness and high in neuroticism experience more incivility (Milam et al., 2009). Traits were assessed with the 12-item scales of neuroticism (e.g., “I often get angry at the way people treat me”) and agreeableness (e.g., “I tend to assume the best about people”) of the French (Aluja, García, Rossier, & García, 2005) and German versions (Borkenau & Ostendorf, 1993; Schmitz, Hartkamp, Baldini, Rollnik, & Tress, 2001) of the NEO Five Factor Inventory Revised (McCrae & Costa, 2004). Participants responded on 5-point scales, ranging from 1 = strongly disagree to 5 = strongly agree. Second, we controlled for gender and age. Women experience more incivility than men (Cortina et al., 2011). Older employees are more discriminated against than their younger counterparts (Gordon & Arvey, 2004), suggesting that they may become targets of selective incivility. Third, we controlled for participants’ activity rate because being more present at the workplace may increase the probability to experience incivility. Activity rate was assessed with the following question: “What is your current rate of work? Take into account all current jobs and consider only paid activities.” Responses were indicated on a 20-category scale, with each category spanning 5% (2.5 hr per week) (1 = 4% or less, 20 = 95% to 100%). Further, we controlled for organizational justice perceptions because low organizational justice is related to higher incidences of workplace aggression in general (Berry, Ones, & Sackett, 2007). Organizational justice was assessed with the short version of the questionnaire by Colquitt (2001), validated by Elovainio et al. (2010), that covers distributive (two items, e.g., “Does your work situation reflect the effort you have put into your work?”), procedural (three items, e.g., “Have you been able to express your views and feelings during those procedures?”) and interpersonal justice (three items, e.g., “Has your supervisor treated you with respect?”). For the interpersonal justice, we omitted one item (“Has your supervisor seemed to tailor his or her communications to individuals’ specific needs?”) because the item was difficult to translate adequately into French and German. Responses were indicated on 5-point scales (1 = to a small extent, 5 = to a large extent).

Results

Hypotheses were tested with multiple regressions, with age, gender, neuroticism, agreeableness, activity rate and organizational justice as control variables,1 nationality (locals vs. German and French immigrants vs. immigrants of other nationalities; dummy-coded) as predictor, and incivility sum scores as criterion.2 To test both the effect of immigrant status (being an immigrant vs. a local) and of immigrant nationality (being a German or French immigrant vs. an immigrant of another nationality) as stated in H1 and H2, two dummy codes for nationality were used that differed with respect to their reference category: locals, in Model 1, and immigrants of nationalities other than French or German in Model 2. For the control variables, results of the final model showed that people with higher activity rates, those high in neuroticism and people perceiving less organizational justice reported more incivility. Further, as expected, German or French immigrant experienced more incivility (M = 6.89, SD = 3.15) than locals (M = 6.42, SD = 2.85) (see Model 1, Table 2). German and French immigrants also experienced more incivility than immigrants of other nationalities (M = 6.31, SD = 2.54; see Model 2, Table 2). However, the latter did not experience more incivility than locals did.

In summary, H1 received partial support: Not all immigrants experienced more incivility than locals; only German and French immigrants did. In support of H2, German and French immigrants experienced more incivility than immigrants of other nationalities. To explore relations between selective incivility and perceived workplace discrimination, we analyzed the joint impact of nationality and incivility on perceived discrimination, using logistic regressions, with perceived discrimination as criterion. As in the previous models, gender, age, activity rate, organizational justice, agreeableness, and neuroticism were entered as control variables. Nationality (dummy-coded, in two sets; see above) and incivility were entered as predictors. Among the control variables, only agreeableness was related to perceived discrimination, B = −0.63, SE = 0.31, Odds Ratio (OR) = 0.54, χ²(9) = 120.49, p < .001, indicating that people low in agreeableness were more likely to report having been discriminated against. Among the main variables, immigrant status was related to perceived discrimination: Both being a German or French immigrant, B = 2.61, SE = 0.31, strong evidence.

Note

1 Adjusted R² = .23, F(8, 1625) = 60.79, p < .001, G/F immigrants = German or French immigrants. Other immigrants = immigrant of nationalities other than German or French. Gender was coded as 0 = male, 1 = female. Age was assessed in years. Activity rate was assessed in percentages (1 = 4% or less, 20 = 95–100%).

2 p < .05. ** p < .01.
OR = 13.47, p < .001, and being an immigrant of another nationality, \( B = 1.99, SE = 0.33, OR = 7.32, p < .001 \), increased the probability to report having been discriminated against. Finally, incivility too was related to perceived discrimination: Experiencing more incivility increased the probability to report having been discriminated against, \( B = 0.17, SE = 0.04, OR = 1.18, p < .001 \).

**Discussion**

This study makes novel contributions to research on workplace discrimination. First, immigrant employees’ experiences of incivility are shown for the first time using a representative sample, drawing attention to an increasingly important but often forgotten minority in the I/O psychology literature (Binggeli, Dietz, & Krings, 2013). Second, it shows that subtle discrimination can be highly selective, mainly targeting those immigrant groups who are perceived as highly competitive and competent but as less likable. This result also underlines that discrimination against immigrants can only be understood when taking the diversity within this group into account. Third, by uncovering relations between experiences of incivility and perceived discrimination for the first time, it provides direct empirical evidence for the claim that selective incivility is indeed a form of discrimination. Finally, it is important to note that effects persisted above and beyond those of personality traits known to influence the experience of discriminatory behaviors.

More specifically, drawing on Cortina’s (2008) model of subtle discrimination, we studied immigrants’ incivility experiences, compared with locals. Results revealed that not all immigrants experienced more incivility than locals. Rather, it was mainly immigrant groups from the immediate neighboring countries, who have multiplied in number during the past decade, and who are very competitive and successful on the local labor market. However, competitiveness costs liking: These groups are perceived as highly competitive and competent but as lacking socioemotional warmth (Binggeli et al., 2013). As such, they receive similar stereotypes such as Asians in the United States do (Lin et al., 2005; Lee & Fiske, 2006), suggesting that this group too may experience higher rates of workplace incivility. The combination of low warmth with high competence may be what makes these groups likely targets of subtle interpersonal discrimination: Whereas their high levels of competence are difficult to deny and (reluctantly or not) given credit for by locals, they are denigrated on warmth, that is, perceived as lacking in warmth and sociability, which may provide the basis for locals to treat them disrespectfully on an interpersonal level.

We also found that immigrant groups were more likely than locals to report having been discriminated against on the basis of their national or ethnic origin, at work, and that these perceptions were, in part, fueled by incivility experiences. This result has at least two implications. First, the linkage between incivility and perceived discrimination corroborates the claim that incivility can be a form of discrimination. It also suggests that while incivility is subtle from the instigator’s perspective, it may be less subtle from the target’s perspective. Second, it underlines the toxic nature of seemingly mild discourteous behaviors at work. Incivility experiences have various negative consequences for targets, for example, for their well-being or organizational commitment (Pearson & Porath, 2004). They also increase intentions to quit (Cortina et al., 2011). Incivility experiences combined with feelings of being discriminated against may further reinforce intentions to leave one’s job and ultimately drive immigrants out of their workplaces.

We controlled for age and gender in our analyses because these groups are often targets of workplace discrimination. However, neither women nor older employees of our study experienced more incivility, which may be explained by several factors. First, unlike earlier studies testing the effects of gender and age (Cortina et al., 2011), we controlled for personality factors when predicting incivility. Indeed, neuroticism was closely related to reports of incivility, corroborating earlier findings (Milam et al., 2009), and underlining the necessity to control for stable individual differences, to isolate the effect of group membership on incivility. Second, analyses were based on a representative sample of the working age population and hence covered employees in a wide range of organizations and occupations. Incivility may be more pronounced in organizational contexts where older employees or women are perceived as “not belonging,” because of social stereotypes, for example, successful women in male-dominated environments (Cortina, 2008; Cortina et al., 2011) or older employees in an organization characterized as young and dynamic (Diekman & Hirnisey, 2007). Finally, the absence of higher incivility rates for older compared with younger employees is in line with earlier findings (Cortina et al., 2011). One explanation may be found in the age limit applied in this study (i.e., age 55), possibly excluding those who would experience the most age discrimination. Another explanation may lie in the older worker stereotype that describes older employees as incompetent (i.e., low in competence) but nice (i.e., high in warmth) (Krings, Szcesny, & Kluge, 2011). Even though mixed stereotypes in general can fuel subtle interpersonal discrimination, results of our study and of other research suggest that the main drivers of interpersonal discrimination may reside with the combination of low warmth and high competence perceptions (Cuddy et al., 2008). Being perceived as incompetent but harmless and trustworthy may actually protect individuals from experiencing interpersonal mistreatments.

**Study Limitations and Future Research**

This study has limitations, and we would like to point out three. First, to participate, immigrants needed sufficient knowledge of one of the two largest national languages. Even though participation required only basic language skills as questions were kept simple, immigrants who did not speak these languages or only very poorly were not included. Further, only legal immigrants with a work permit were included. Consequently, illegal immigrants or immigrants that were less well integrated or well off, because of language problems, were not represented. Reaching these groups is a general and recurrent difficulty in survey research with immigrants (Laganá, Elcheroth, Penic, Kleiner, & Fasel, 2013). However, they make up an important part of the immigrant population, and they are likely to experience discrimination. To attain a more complete picture of immigrants’ work experiences, future research should invest more efforts to include them.

Second, effects of immigrant status on incivility and of incivility on perceived discrimination were significant but modest. This may be because of the fact that analyses were based on a large representative sample and hence included a wide array of possible
