5
6 We thank Nevez and Le Gal for their interest in our work, and to underscore its importance
7 (1). Our results strongly suggest that *Pneumocystis jirovecii* infecting humans is sensitive to
8 caspofungin, like are the *Pneumocystis* species infecting rodents used as models. Thus, we
9 fully agree with Nevez and Le Gal that the usefulness of caspofungin to treat *Pneumocystis*
10 pneumonia should be considered for clinical use. In addition, the sensitivity of *P. jirovecii* to
11 the other echinocandins used clinically will have to be characterized. Indeed, *Saccharomyces*
12 *cerevisiae* harbors three differentially regulated genes encoding the target of the
13 echinocandins, the catalytic subunit of the 1,3- β -glucan synthase. Despite close homology,
14 these enzymes present drastically distinct sensitivities to the different echinocandins,
15 caspofungin, anidulafungin, and micafungin (1-3). The *Pneumocystis* species infecting
16 rodents proved to be sensitive to the three echinocandins (4, 5). Nevertheless, because the
17 homology between the enzymes of the different *Pneumocystis* species is similar to that
18 between the three *S. cerevisiae* enzymes (1), one cannot exclude that *P. jirovecii* is insensitive
19 to anidulafungin and micafungin.
