## DIFFANTOM IN BRIEF

*Diffantom* is a whole-brain diffusion MRI (dMRI) phantom publicly available through the Dryad Digital Repository (doi:10.5061/dryad.4p080). The dataset contains two single-shell dMRI images, along with the corresponding gradient information, packed following the BIDS standard (Brain Imaging Data Structure, Gorgolewski et al., 2015). The released dataset is designed for the evaluation of the impact of susceptibility distortions and benchmarking existing correction methods.

In this Data Report we also release the software instruments involved in generating *diffantoms*, so that researchers are able to generate new phantoms derived from different subjects, and apply these data in other applications like investigating diffusion sampling schemes, the assessment of dMRI processing methods, the simulation of pathologies and imaging artifacts, etc. In summary, *Diffantom* is intended for unit testing of novel methods, cross-comparison of established methods, and integration testing of partial or complete processing flows to extract connectivity networks from dMRI.

## INTRODUCTION

Fiber tracking on dMRI data has become an important tool for the *in vivo* investigation of the structural configuration of fiber bundles at the macroscale. Tractography is fundamental to gain information about white matter (WM) morphology in many clinical applications like neurosurgical planning (Golby et al., 2011), post-surgery evaluations (Toda et al., 2014), and the study of neurological diseases as in Chua et al. (2008) addressing multiple sclerosis and Alzheimer's disease. The analysis of structural brain networks using graph theory is also applied on tractography, for instance in the definition of the unique subject-wise patterns of connectivity (Sporns et al., 2005), in the assessment of neurological diseases (Griffa et al., 2013), and in the study of the link between structural and functional connectivity (Messé et al., 2015). However, the development of the field is limited by the lack of a gold standard to test and compare the wide range of methodologies available for processing and analyzing dMRI.

Large efforts have been devoted to the development of physical phantoms (Lin et al., 2001; Campbell et al., 2005; Perrin et al., 2005; Fieremans et al., 2008; Tournier et al., 2008). Côté et al. (2013) conducted a thorough review of tractography methodologies using the so-called *FiberCup* phantom (Poupon et al., 2008; Fillard et al., 2011). These phantoms are appropriate to evaluate the angular resolution in fiber crossings and accuracy of direction-independent scalar parameters in very simplistic geometries. Digital simulations are increasingly popular because the complexity of whole-brain tractography can not be accounted for with current materials and proposed methodologies to build physical phantoms. Early digital phantoms started with simulation of simple geometries (Basser et al., 2000; Gössl et al., 2002; Tournier et al., 2002; Leemans et al., 2005) to evaluate the angular resolution as well. These tools generally implemented the multi-tensor model (Alexander et al., 2001; Tuch et al., 2002) to simulate fiber crossing, fanning, kissing, etc. Close et al. (2009) presented the *Numerical Fiber Generator*, a software to simulate spherical shapes filled with digital fiber tracts. Caruyer et al. (2014) proposed *Phantomas* to simulate any kind of analytic geometry inside a sphere. *Phantomas* models diffusion by a restricted and a hindered compartment, similar to Assaf and Basser (2005). Wilkins et al. (2015) proposed a whole-brain simulated phantom derived from voxel-wise orientation of fibers averaged from real dMRI scans and the multi-tensor model with a compartment of isotropic diffusion. Neher et al. (2014) proposed *FiberFox*, a visualization software to develop complex geometries and their analytical description. Once the geometries are obtained, the software generates the corresponding dMRI signal with a methodology very close to that implemented in *Phantomas*. An interesting outcome of *FiberFox* is the phantom dataset<sup>1</sup> created for the Tractography Challenge held in ISMRM 2015. This dataset was derived from the tractography extracted in one Human Connectome Project (HCP, Van Essen et al., 2012) dataset. In the tractogram, 25 fiber bundles of interest were manually segmented by experts. Using *FiberFox*, the segmentation of each bundle was mapped to an analytical description, and finally simulated the signal.

In this data report we present *Diffantom*, an *in silico* dataset to assess tractography and connectivity pipelines using dMRI real data as source microstructural information. *Diffantom* is inspired by the work of Wilkins et al. (2015), with two principal novelties. First, since we use a dataset from the HCP as input, data are already corrected for the most relevant distortions. The second improvement is a more advanced signal model to generate the phantom using the hindered and restricted diffusion model of *Phantomas* (Caruyer et al., 2014). As a result, we provide a whole-brain digital phantom of dMRI data with structural information derived from an HCP dataset. We also openly release the *diffantomizer* workflow, the software package necessary to generate custom *diffantoms*. *Diffantom* is originally designed for the investigation of susceptibility-derived distortions, a typical artifact that produces geometrical warping in certain regions of dMRI datasets. In Esteban et al. (2014) we addressed this phenomenon and concluded that the connectivity matrix of

*Phantomas* was not dense enough to evaluate the integration of correction methods in pipelines for the connectome extraction.

## DATA DESCRIPTION

### Microstructural Model

The simulation process relies on a microstructural model derived from real data. On one hand, the *diffantomizer* workflow requires up to five fraction maps  $\{T_j | j \in \{1, \dots, 5\}\}$  of free- and hindered- diffusion (see **Figure 1A**). These compartments will be derived from the macroscopic structure of tissues within the brain, specified in the following order<sup>2</sup>: cortical gray matter (cGM), deep gray matter (dGM), WM, CSF, and abnormal tissue<sup>3</sup>. On the other hand, the restricted-diffusion compartments are specified by up to three volume fractions  $\{F_i | i \in \{1, 2, 3\}\}$  of three single fiber populations per voxel along with their corresponding direction maps  $\{\mathbf{V}_i | i \in \{1, 2, 3\}\}$ .

The process to obtain the microstructural model from one dataset of the HCP can be described as follows (see also **Figure 1B**): (1) The fiber orientation maps  $\{\mathbf{V}_i\}$  and their corresponding estimations of volume fraction  $\{F'_i\}$  are obtained using the ball-and-stick model for multi-shell data of BEDPOSTX (Bayesian Estimation of Diffusion Parameters Obtained using Sampling Techniques modeling crossing – X– fibres, Jbabdi et al., 2012) on the dMRI data. The HCP recommends BEDPOSTX to reconstruct their data (Glasser et al., 2013). A further advantage is that BEDPOSTX exploits the multi-shell acquisitions of the HCP while operating at whole-brain level. (2) A fractional anisotropy (FA) map is obtained after fitting a tensor model with *MRTrx*. As we shall see in the Appendix, the FA is used to infer  $F_1$  (the fraction map of the most prevalent fiber), avoiding the extremely noisy estimation of  $F'_1$  performed by BEDPOSTX in the previous step. (3) The original fiber fractions  $\{F'_i\}$  and the FA map are denoised with a non-local means filter included in *dipy* (Garyfallidis et al., 2014). This step produces an important smoothing of the maps, while preserving the edges. Smoothing is also beneficial in simplifying the voxel-wise diffusion model. (4) The macrostructural fractions  $\{T'_j\}$  are extracted from the T1-weighted image of the dataset, using standard *FSL* segmentation tools (Jenkinson et al., 2012). (5) The images obtained previously (FA map,  $\{\mathbf{V}_i\}$ ,  $\{F'_i\}$ , and  $\{T'_j\}$ ) are combined as described in the Appendix to generate the final microstructural model ( $\{\mathbf{V}_i\}$ ,  $\{F_i\}$ , and  $\{T_j\}$ ), presented in **Figure 1A**.

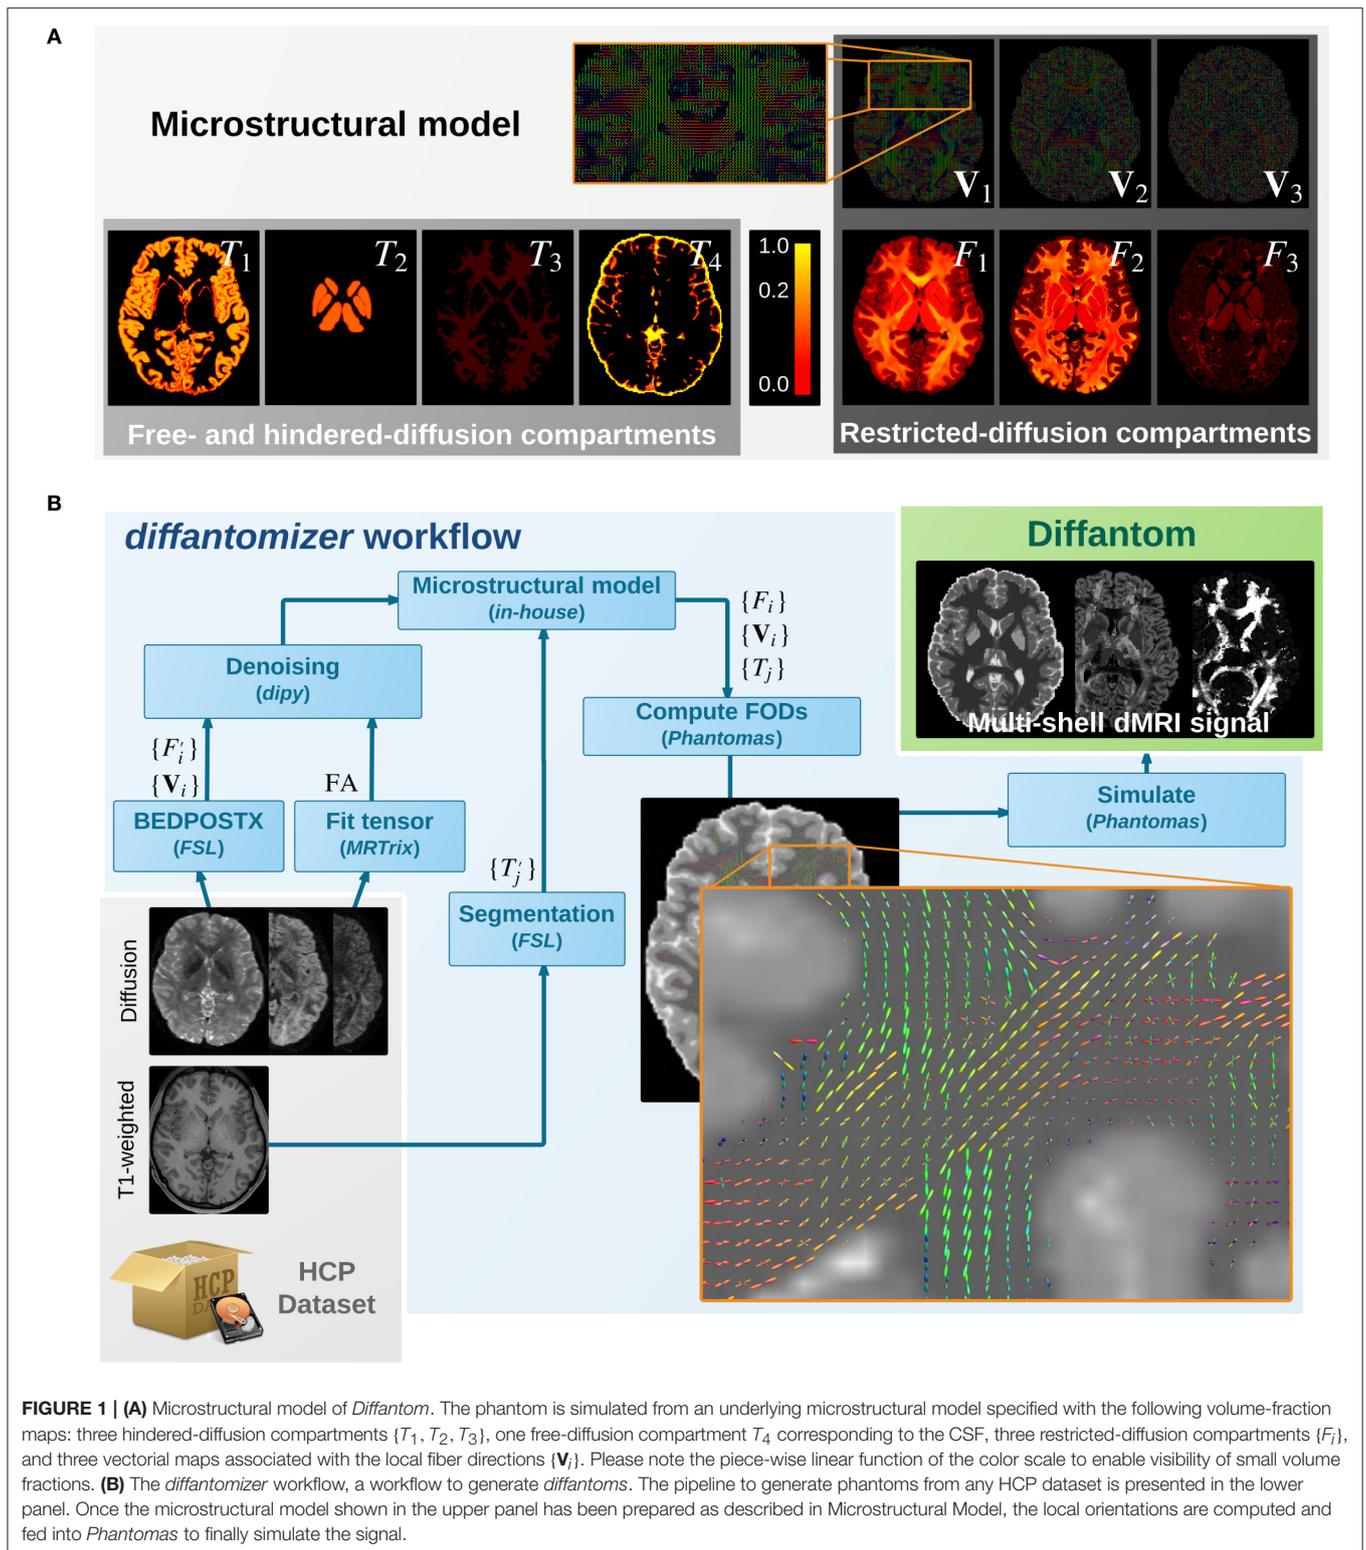

### Diffusion Signal Generation

Once a microstructural model of the subject has been synthesized, the fiber orientation maps  $\{\mathbf{V}_i\}$  are weighted by the fiber-fraction maps  $\{F_i\}$  and projected onto a continuous representation of the fiber orientation distributions (FODs). A close-up showing how the FODs map looks is presented in **Figure 1B**. The single fiber response is a Gaussian diffusion

<sup>2</sup>Corresponding to the *5TT format* established with the latest version 3.0 of *MRTrx* (Tournier et al., 2012).

<sup>3</sup>Since here we simulate healthy subjects, the last fraction map  $T_5$  is empty and can be omitted.

<sup>1</sup>Available at: [http://www.tractometer.org/ismrm\\_2015\\_challenge/](http://www.tractometer.org/ismrm_2015_challenge/).

**FIGURE 1 | (A)** Microstructural model of *Diffantom*. The phantom is simulated from an underlying microstructural model specified with the following volume-fraction maps: three hindered-diffusion compartments  $\{T_1, T_2, T_3\}$ , one free-diffusion compartment  $T_4$  corresponding to the CSF, three restricted-diffusion compartments  $\{F_i\}$ , and three vectorial maps associated with the local fiber directions  $\{V_j\}$ . Please note the piece-wise linear function of the color scale to enable visibility of small volume fractions. **(B)** The *diffantomizer* workflow, a workflow to generate *diffantoms*. The pipeline to generate phantoms from any HCP dataset is presented in the lower panel. Once the microstructural model shown in the upper panel has been prepared as described in Microstructural Model, the local orientations are computed and fed into *Phantoms* to finally simulate the signal.

tensor with axial symmetry and eigenvalues  $\lambda_1 = 2.2 \cdot 10^{-3} \text{ mm}^2\text{s}^{-1}$  and  $\lambda_{2,3} = 0.2 \cdot 10^{-3} \text{ mm}^2\text{s}^{-1}$ . The resulting FODs map is then combined with the free- and hindered-diffusion compartments corresponding to  $\{T_j\}$ . The free-diffusion

compartment corresponds to the CSF fraction map  $T_4$  and is modeled with isotropic diffusivity  $D_{CSF}$  of  $3.0 \cdot 10^{-3} \text{ mm}^2\text{s}^{-1}$ . The hindered-diffusion compartments correspond to  $\{T_1, T_2, T_3\}$  and are also modeled with isotropic diffusivity

$D_{WM} = 2.0 \cdot 10^{-4}$ ,  $D_{CGM} = 7.0 \cdot 10^{-4}$  and  $D_{dGM} = 9.0 \cdot 10^{-4}$ , respectively [ $\text{mm}^2\text{s}^{-1}$ ]. All these values for diffusivity (and the corresponding to the single-fiber response) can be modified by the user with custom settings. The restricted- and hindered-compartments are then fed into *Phantomas* (Caruyer et al., 2014) and the final dMRI signal is obtained. By default, diffusion data are generated using a scheme of 100 directions distributed in one shell with uniform coverage (Caruyer et al., 2013). Custom one- or multi-shell schemes can be generated supplying the tables of corresponding vectors and  $b$ -values. Rician noise is also included in *Phantomas*, and the signal-to-noise ratio (SNR) can be set by the user. The default value for SNR is preset to 30.0.

## Implementation and Reproducibility

We also provide the *diffantomizer* workflow, the software package used to generate *diffantoms*, so that users can regenerate similar datasets with different parameters. This workflow, presented in **Figure 1**, is implemented using *nipy* (Gorgolewski et al., 2011) to ensure reproducibility and usability.

## Interpretation and Recommended Uses

To illustrate the features of *Diffantom*, the example dataset underwent a simplified connectivity pipeline including constrained spherical deconvolution (CSD) and probabilistic tractography from *MRTrix* (Tournier et al., 2012). CSD was reconstructed using 8th-order spherical harmonics, and tractography with  $1.6 \cdot 10^6$  seed points evenly distributed across a dilated mask of the WM tissue. **Figures 2A1,A3**, show the result of the tractography obtained with such pipeline for the original *Diffantom* and a distorted version. Finally, we applied *tractquerier* (Wassermann et al., 2013) to segment some fiber bundles such as the CST and the forceps minor (see **Figures 2A2,A4**). Particularly, due to its location nearby the orbitofrontal lobe, the forceps minor is generally affected by susceptibility distortions.

We recommend *Diffantom* as ground-truth in verification and validation frameworks (**Figure 2B**) for testing pipelines. *Diffantom* is applicable in the unit testing of algorithms, the integration testing of modules in workflows, and the overall system testing. Some potential applications follow:

- Investigating the impact of different diffusion sampling schemes on the local microstructure model of choice and on the subsequent global tractography outcome. Since the gradient scheme can be set by the user, *Diffantom* can be seen as a mean to translate the so-called  $b$ -matrix of the source dataset to any target scheme.
- Assessment of sensitivity and robustness to imaging artifacts (noise, partial volume effect and CSF contamination, susceptibility-derived warping, Eddy-currents-derived distortions, etc.) at unit, integration and systems testing levels.
- Using *Diffantom* as in **Figure 2B**, it is possible to apply binary classification measures to evaluate the resulting connectivity matrix. Considering the connectivity matrix of the *reference Diffantom* and the resulting matrix of the *test Diffantom*, the receiver operating characteristic (ROC) of the pipeline can be characterized.

- Simulation of pathological brains by altering the microstructural model accordingly (e.g., as tumors were simulated in Kaus et al., 2000).

In order to exemplify one of these intended uses, we also release a *Diffantom* including the susceptibility-derived distortion in simulation. These two images belong to a broader dataset, automatically generated, used in a study to quantify the impact of susceptibility distortions and correction methods on the connectome extraction (Esteban, 2015, Chapter 5). In this study, three widely-used correction methods are compared in a reference framework of several *Diffantoms* with realistic and controlled distortions. This context provides a useful resource to characterize the impact of susceptibility distortion on the final connectivity network and allows the evaluation of the different correction methodologies available.

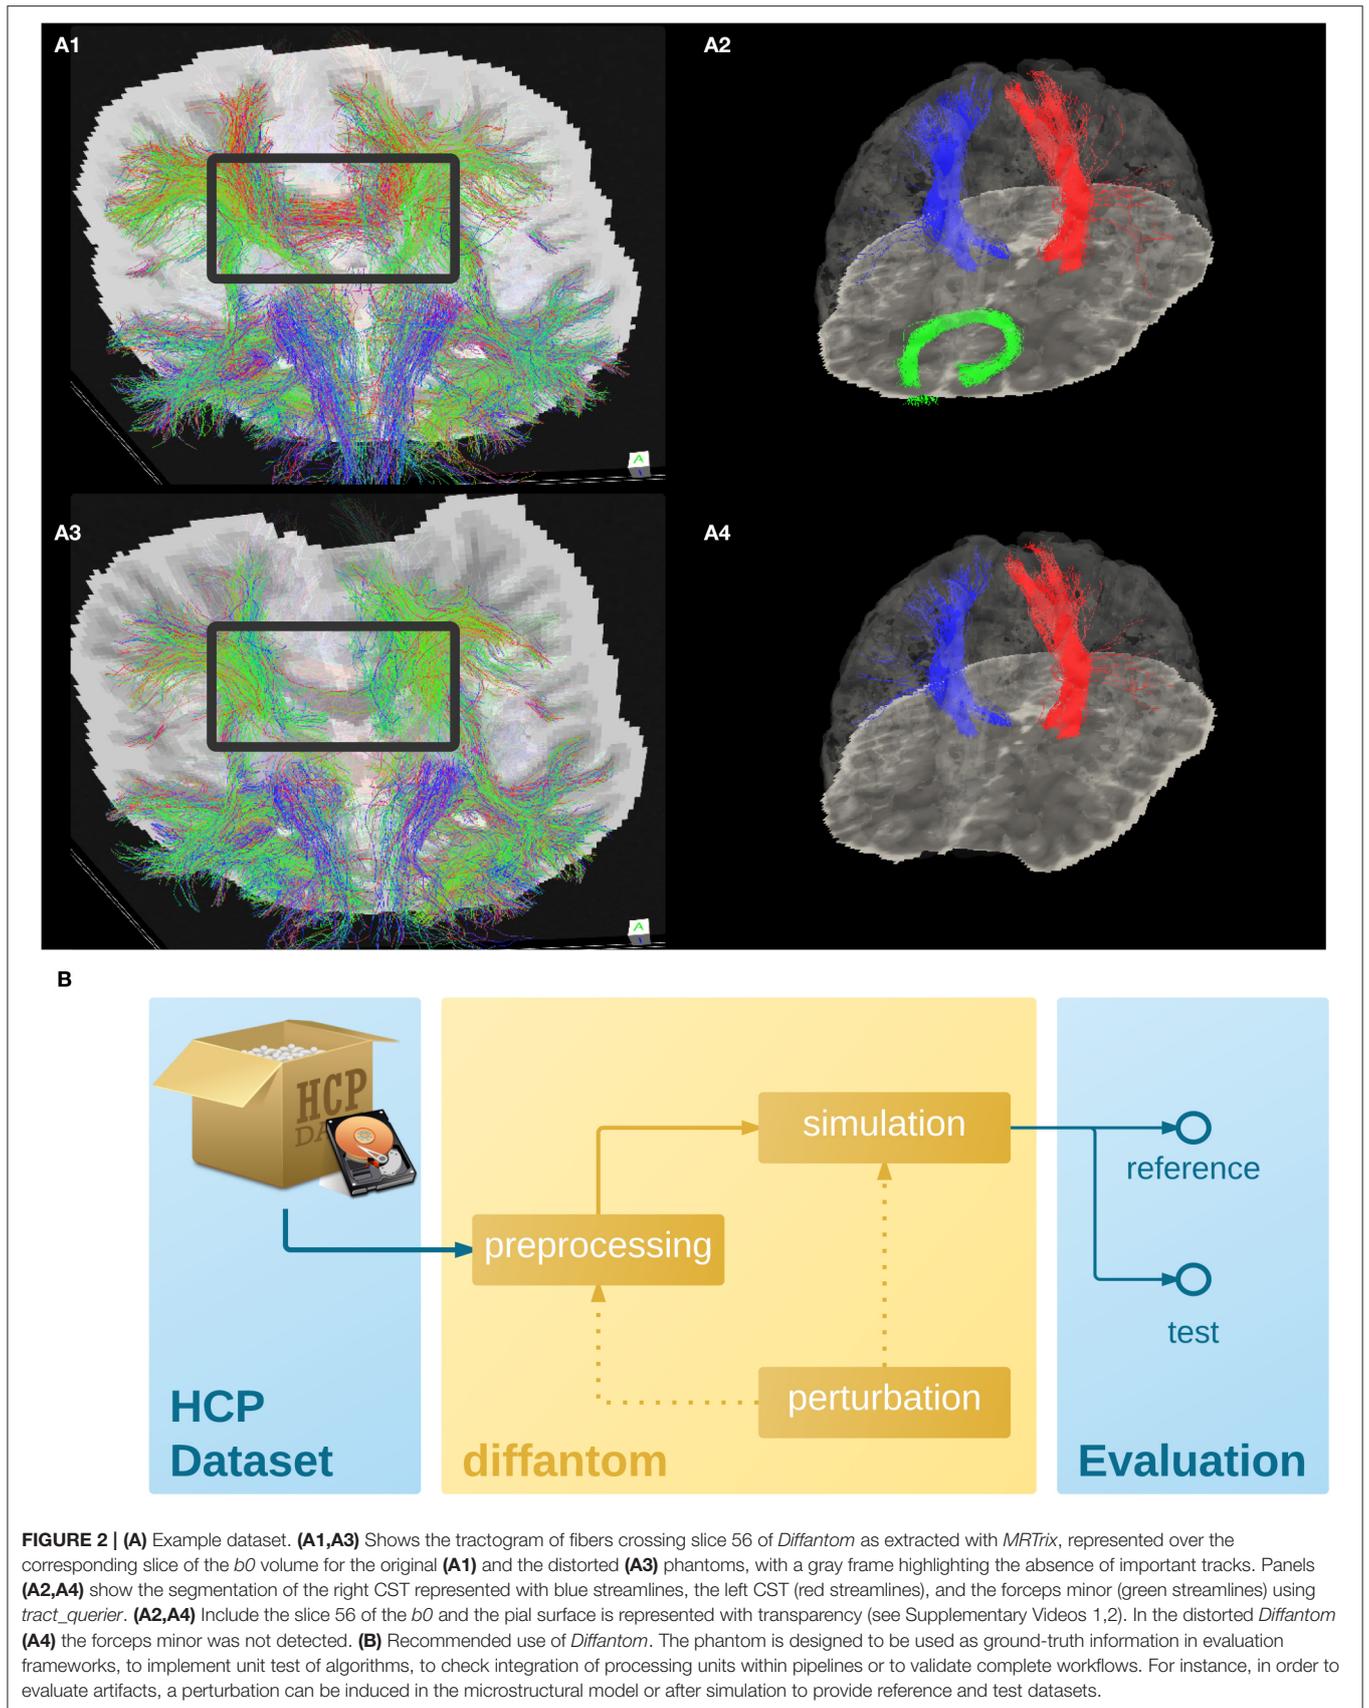

## DISCUSSION

Whole-brain, realistic dMRI phantoms are necessary in the developing field of structural connectomics. *Diffantom* is a derivative of Wilkins et al. (2015) in terms of methodology for simulation with two major advances. First, the correctness of the *minimally preprocessed* data (Glasser et al., 2013) released within the HCP. Wilkins et al. (2015) explicitly state that their original data were not corrected for certain artifacts, and thus, generated data are affected correspondingly. Second, *Diffantom* implements the hindered and restricted compartments model (Assaf and Basser, 2005), which is a more complete model than the multi-tensor diffusion model.

A possible competitor to *Diffantom* is the phantom generated for the Tractography Challenge in ISMRM 2015. Similarly to *Diffantom*, the organizers used an HCP subject as source of structural information. While this phantom is designed for the bundle-wise evaluation of tractography (with the scores defined in the *Tractometer* (Côté et al., 2013), such as geometrical coverage, valid connections, invalid connections, missed connections, etc.), *Diffantom* is intended for the connectome-wise evaluation of results, yielding a tractography with a large number of bundles. Therefore, *Diffantom* and *FiberFox* are complementary as the hypotheses that can be investigated are different. Moreover, *Diffantom* does not require costly manual segmentation of bundles, highly demanding in terms of physiology expertise and operation time. The software workflow released with this data report (the *diffantomizer*) ensures the reproducibility of *Diffantom* and enables the generation of custom *diffantoms*. The *diffantomizer* is designed for, but not limited to, use HCP datasets as source of structural information.

## CONCLUSION

*Diffantom* is a whole-brain digital phantom generated from a dataset from the Human Connectome Project. *Diffantom* is presented here to be openly and freely distributed along with the *diffantomizer* workflow to generate new *diffantoms*. We

encourage the neuroimage community to contribute with their own *diffantoms* and share them openly.

## DATA SHARING

The first *Diffantom* and its distorted version are available under the Creative Commons Zero licence (CC0) using the Dryad Digital Repository (doi:10.5061/dryad.4p080). The package is organized following the BIDS standard. The associated software to “*diffantomize*” real dMRI datasets is available at <https://github.com/oesteban/diffantom> under an MIT license. *Phantomas* is available in <https://github.com/ecaruyer/Phantomas> under the revised-BSD license.

## AUTHOR CONTRIBUTIONS

All the authors contributed to this study. OE designed the data generation procedure, implemented the processing pipelines and generated the example dataset. EC implemented *Phantomas* (Caruyer et al., 2014), helped integrate the project with the simulation routines. OE, EC, AD thoroughly discussed and framed the aptness of the data in the community. AD, MB,

ML, and AS interpreted the resulting datasets. MB, ML, and AS advised on all aspects of the study.

## FUNDING

This study was supported by the Spanish Ministry of Science and Innovation (projects TEC-2013-48251-C2-2-R and INNPACTO XIORT), Comunidad de Madrid (TOPUS) and European Regional Development Funds, the Center for Biomedical Imaging (CIBM) of the Geneva and Lausanne Universities and the EPFL, as well as the Leenaards and Louis Jeantet Foundations.

## ACKNOWLEDGMENTS

We thank Gert Wolny for his revision of this work.

## SUPPLEMENTARY MATERIAL

The Supplementary Material for this article can be found online at: <http://journal.frontiersin.org/article/10.3389/fninf.2016.00004>
